**Über dieses Buch**

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

**Nutzungsrichtlinien**

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

**Über Google Buchsuche**

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

### LITHOLAPAXY, OR LITHOTRITY AT A SINGLE SITTING. (a)

By WILLIAM STOKES, F.R.C.S.,

Professor of Surgery, Royal College of Surgeons, Surgeon to Richmond Surgical Hospital.

The following case is, I think, worthy of record, being one in which I performed the operation of lithotrity first in the August of last year, when I removed after four sittings a phosphatic calculus weighing 86 grs., and again in July of the present year, when I removed a calculus weighing 56 grs. by a different method, viz., the one to which Prof. Bigelow has given the name of "Litholapaxy." The case was of a man æt. 60, who was first admitted into the Richmond Surgical Hospital on August 19th, 1878. For two years he had suffered acutely from all the ordinary symptoms of stone, which are unnecessary here to recapitulate. On sounding the patient the stone was at once struck. On August 22nd I performed lithotrity in the ordinary manner, and repeated the operation on Aug. 29th, again on September 9th, and lastly on September 19th—four crushings in all. After these operations no trace of calculus could be detected on careful examination being made by my colleagues and myself, and the patient expressed himself as relieved from all vesical trouble. After the second and fourth crushings very grave constitutional disturbances were observed, especially after the last; so much so as to give rise to serious apprehensions on my part as to the result. However, eventually the patient recovered and returned home, free from all the pain and vesical irritation he had so long suffered from. Immunity from the trouble, however, was not destined to be of long duration. In about six months after the patient left the hospital, the pain and frequent desire to micturate again commenced, and on his readmission into hospital four months subsequently, a calculus was again found to exist. As there appeared to be no contra-indication to the adoption of Bigelow's method of operating, I determined to adopt it in this case, especially as I had a vivid recollection of the alarming symptoms the patient had after the former lithotrity operations; I determined therefore, if possible, to remove the stone at one sitting. On July 17th, assisted by my colleagues—Drs. Thomson and Corley—I operated, using the straight evacuating catheter No. 18. This was introduced with facility after the orifice of the urethra was enlarged by incision. The operation lasted an hour and ten minutes, and a calculus weighing 56 grains—and which I have now the opportunity of exhibiting to the Society—was removed. Thompson's full-sized lithotrite was employed, and introduced three times during the operation. A half-grain morphia suppository was then administered, and he soon after fell asleep. At seven o'clock p.m. the patient had a violent rigor, and both pulse and temperature rose. Diffusible stimulants and opium were then given, and no recurrence of these symptoms was subsequently observed. On the fourth day after the operation severe abdominal pain was complained of, which, however, completely yielded to the exhibition of opium. There was no recurrence of it. On the ninth day after the operation the patient expressed himself as relieved from all vesical trouble, and on the twelfth day left the hospital at his own request. I have seen the patient twice since he left the hospital, and on both occasions he expressed himself as completely free from the distress he had so long suffered from.

As this was, so far as I am aware, the first time the operation of Bigelow was performed in Ireland, a few observations in reference to the procedure and its alleged advantages will not, I trust, be considered inappropriate.

First, as regards the name—"Litholapaxy"—given to it by Professor Bigelow. This designation would to most persons seem to imply that the procedure, denoting by its derivation a washing out of stone from the bladder, was a novel operation; but, as a matter of fact, this mode of removing calculous debris is the reverse of novel, having been unquestionably first suggested and practised in the manner I shall presently draw attention to by your late distinguished countryman Sir Philip Crampton, in the Meath Hospital, many years ago. It was also practised by the late Sir Benjamin Brodie, as I have learned from Sir Henry Thompson; by French surgeons; and lastly by Mr. Clover, whose india-rubber bottle and glass receiver was first used by Sir Henry Thompson many years ago, and doubtless familiar to every operating surgeon here present.

---

(a) Read before the Surgical Society of Ireland. Discussion will be found on page 5.

Mr. Porter, in one of his eminently practical communications on lithotrity, states that he has seen Sir Philip Crampton employ his ingenious contrivance on several occasions in the Meath Hospital. The apparatus which, through the kindness of our ex-President, Mr. Smyly, I am able to exhibit, and also the illustration of it, in which occurs the paper by Mr. Porter to which I have already alluded, consists of a strong oval-shaped vessel of glass or copper, capable of containing about a pint and a-half of water. The air in the vessel is then exhausted and attached to an evacuating catheter. Communication is then established between the bladder and the glass vessel by turning the stop-cock, and the pressure of the atmosphere on the bladder supplies an expulsive force which, as Sir P. Crampton observed, "may be increased to any required amount." Although the apparatus of Clover is doubtless an improvement on that of Crampton—the chief improvement being the substitution of a caoutchouc bag for the oval copper or glass bottle—many lithotritists of eminence, notably Professor Gross, of Philadelphia, and M. Voillemier, have expressed themselves unfavourably as regards the utility of any evacuating apparatus, the former going so far as to say that in his opinion its use "is as irritating as lithotrity itself." The majority of surgeons, however, who have had experience in lithotrity, will be more inclined to endorse the generally accepted view that the vesical irritation and cystitis which so frequently hitherto have followed lithotrity, have been more closely connected with the presence of calculous débris in the bladder than with the use of the evacuating aspirator. At a comparatively recent meeting of the Royal Medico-Chirurgical Society of London, the great liability of cystitis following lithotrity, and which was mainly attributed to the injury done to "the mucous membrane by sharp fragments of stone and by continued instrumentation," was fully described, and Sir James Paget remarked, that "were he to recommence surgical life he would begin with lithotomy, and reserve for lithrotrity only those few cases in which the stone could be got rid of in two or three sittings." Sir H. Thompson observed that in addition to the cases in which the calculus could be got rid of in two or three sittings, he would include those "where the stone might be crushed in three, or at most four sittings," beyond which point "he would mostly prefer to cut." Such were the views held up to March, 1878, and had no change subsequently been made in the operation, these sentiments, coming from surgeons of such deserved eminence, would doubtless have proved the death-knell of lithotrity.

Doubtless one chief reason why the evacuating apparatuses hitherto in use have met with the marked disapproval of the French and American surgeons I have already mentioned, has been the small size of the evacuating catheters attached to them, rendering frequent and often protracted sittings necessary. The investigations of Otis and Van Buren have demonstrated that the calibre of the urethra is much greater than had hitherto been generally supposed. I am not prepared to say with Prof. Otis that the average capacity of the *normal* urethra corresponds to 33 Charrière, but the fact that Bigelow's straight evacuating tubes can be introduced with such comparative ease proves the truth of Prof. Otis's statements as regards the urethral calibre generally. It is obvious, too, that the tube being, as a rule, straight, or nearly so, as in Sir H. Thompson's aspirator, facilitates largely the evacuation of the calculous fragments.

The first improvement, therefore, in Bigelow's method of performing lithotrity is the use of an evacuating catheter of such large dimensions as to permit the exit of very large calculous fragments, which, when left in the bladder, so frequently induce cystitis. Its being straight, too, is an obvious advantage. It has been supposed by many that the difficulties in passing the straight instrument would be very great. Such, however, I may say, is not the case. The natural obstruction at the triangular ligament is the only one that at times may cause some trouble in overcoming. On this Bigelow observes:—"Having reached this point, which implies that there should be no premature endeavour to turn the instrument, but that it should be passed as far as it will go in the general direction of the anus before its direction is changed, the extremity of the instrument depresses the floor of the urethra in front of the ligament. Traction upon the penis next effaces this depression, and adds firmness to the urethral walls, so that if the instrument be withdrawn a little, and again advanced after lowering the handle, it can be coaxed without difficulty through the ligament in question—a natural obstruction which physicians often mistake for stricture. The straight tube may be *advantageously rotated through the aperture like a corkscrew.*" This manœuvre I adopted in the case I have drawn attention to, and found no difficulty in passing the instrument.

The apparatus of Bigelow is a larger and more powerful one than Clover's, communicating at its upper end with the long evacuating catheter by means of a long india-rubber tube. At the lower end of the bottle is the glass receiver for the calculous débris. Mr. Teevan considers the interposition of the india-rubber tubing between the catheter and the bulb to be of great advantage, as it prevents any jerking of the catheter during the evacuating process. "All other aspirators," he observes, "are fixed directly on to the catheter, so that every time the ball is compressed the catheter is jerked, to the great annoyance of the patient. If the patient be under ether, the disadvantage still exists, for the continual disturbance of the catheter irritates the bladder and produces hæmorrhage."

Sir Henry Thompson has recently devised an apparatus for removing the fragments after lithotrity, which is very perfect and ingenious in its construction. A description of the apparatus appeared in a recent number of the *Gazette Hebdomadaire*, a copy of which, containing an illustration, he kindly sent me for exhibition on this occasion. It will be seen that there is in it a direct communication between the aspirator and the evacuating catheter. The chief advantages of the apparatus are that the fragments from the bladder reach the glass receiver by the shortest route, and the current from the bulb, not having the tubing to traverse, has more direct action on the fragments to be removed. The introduction of air into the bladder is also rendered impossible, and this is, I think, a great advantage which the instrument possesses over Bigelow's aspirator.

As regards the lithotrite, the instrument advocated by Bigelow is a very much larger and more powerful one than those hitherto usually employed. On each side of the male blade are a series of triangular notches, and close to the angle of the female blade are two slots, through which is driven any of the débris not discharged laterally by the notches. Also to prevent the liability of the bladder being nipped in the instrument, the shoe of the female blade is made wider and longer than usual, in order to repel the vesical walls. Mr. Teevan considers this instrument cumbersome, and prefers Mercier's lithotrite. The stone in the case I operated on being a soft one, a lithotrite of special strength and calibre was unnecessary, so I used one made by Collin on the same principle as that of Sir H. Thompson. He also considers, I may mention, that the employment of the large, clumsy, cumbersome lithotrites of Bigelow are in all cases unnecessary and undesirable, the instruments more usually employed being "more efficient, safe, and speedy in their action."

In these particulars connected with the operation, full credit, I think, must be given to Prof. Bigelow, viz., strengthening the elastic bottle, enlarging the evacuating catheter to allow of the exit of large fragments of calculous débris, and—most important of all—proving the tolerance by the bladder of protracted manipulation. "Personally," says Prof. van Buren, "I feel much confidence that Prof. Bigelow's novel proposition that lithotrity may be safely accomplished at one sitting will be successfully demonstrated, and that his discovery of the hitherto unrecognised tolerance of the bladder—for it certainly is to be regarded as a discovery in the true sense of the term—will by its great practical value modify the future of lithotrity."

Already the experience—necessarily a limited one—of the operation goes far to show that the future of lithotrity is likely to be signally modified by Bigelow's method of performing the operation, for so far as I have been able to ascertain, the experience of those who have tested the operation has been so far most favourable.

Mr. Teevan has operated three times on patients aged respectively 88, 75, and 60, and the result was in each case all that could be desired. He has expressed himself as impressed, among other things, with the slight amount of constitutional disturbance set up by the operation, the absence of pain, the rapidity with which the urine clears, and that the method so completely clears the bladder that only dust, or pieces the size of millet seeds, pass the day after the operation. Mr. Coulson has also, I am informed, operated on three hospital patients with good results. So has also Mr. Buckstone Brown; and in a paper on a series of thirteen cases published by Sir Henry Thompson in the *British Medical Journal* for Aug. 2nd, 1879, the advantages of the procedure are fully recognised. He observes:—"I have no hesitation in stating that we owe to Prof. Bigelow the assurance that so much manipulation is tolerated by the bladder in the process of removing the stone, provided we take it away entirely, or nearly so. It is quite true that the presence of sharp broken fragments in that viscus does more damage to it than the prolonged, but of course careful, use of instruments for their removal."

The advantages referred to above were clearly observed by me, not only in the case I have already given briefly the chief particulars of, but also in one that occurred in Dr. Atthill's practice, a lady, from whose bladder he removed, last August, by Bigelow's aspirator, a calculus, at which operation I had the pleasure of assisting. Although doubtless much credit is due to Prof. Bigelow for improving the operation in the manner already mentioned, yet I think the majority of surgeons will agree with the views of Sir Henry Thompson as stated in a recent valuable communication to me on this subject, to the effect that these improvements of Bigelow—and we must admit them to be such—hardly justify the attachment of a new and not very euphonious name to an operation already designated correctly by Civiale, and others, as lithotrity. Sir H. Thompson, however, fully recognises the merits of Bigelow's procedure, for he states that to him "belongs the credit of venturing to clear out a bladder at one sitting so as to avoid the irritation of fragments left there afterwards; and I do not hesitate to say that my experience, partly given in the *British Medical Journal*, August 2, 1879, and since, leads me to believe that in many cases a better result will be obtained by venturing on a crushing more prolonged than has hitherto been customary, provided all, or nearly all, the stone is removed. This aspect of the operation is the new one, and not the washing out." In place, therefore, of the term "litholapaxy," which, etymologically considered, is merely a washing out of the stone, and which might equally well be applied to Sir Philip Crampton's method as to Bigelow's, it would be far more logical, more just, and more courteous to the Fathers of Lithotrity, Crampton, Civiale, Brodie, and others, to retain the term they applied, "lithotrity," and adopt the definition proposed by Sir H. Thompson of "lithotrity at a single sitting."

## A CASE OF SCARLET FEVER OR DIPHTHERIA.

By WILLIAM H. PEARSE, M.D. Edin.

Physician to the Plymouth Public Dispensary.

C. J., æt. 6, in October 22nd, 1876, was in his usual good health; he became hot at night, and on the next day I found a white patch of slough on one tonsil. I had no anxiety about the throat; no local application was made to it: the well-defined white patch of slough separated in a few days, and the throat was well. I ordered cod-liver oil, and a mixture of bark and chlorate of potass; also a little claret. He, however, took little or none of them, for his parents did not like to force him against his temper. He was kept in, and warmly clad. Two months prior to his attack, his sister had had scarlet fever. About November 8th, pain and swelling came on in the joints of the tarsus and knees, but did not continue longer than five days. The boy continued to get thin; the appetite was bad. On November 24th albuminuria showed. About November 28th the earliest brain symptoms showed; the left upper eye-lid fell; the left eye squinted; drink, when attempted to be swallowed, returned through the nostrils; and there was considerable paralysis of motion of left arm and leg. Iodide and bromide of potassium were given, and mercurial inunction used; the fullest support of food was given. About December 16th, the brain symptoms began to pass off; the ptosis and squint disappeared. His gait continued tottering up to the end of January, 1877.

The temperature and pulse records were: Nov. 23, temp., 98·4 deg.; 28th, temp., 99·4 deg.; pulse, 128; 30th, temp., 100 deg.; pulse, 144. Dec. 1st, temp., 100 deg.; pulse, 126; 3rd, temp., 97·4 deg.; 4th, temp., 98 deg.; 5th, temp., 98·6 deg.; 8th, temp., 97·8 deg.; pulse, 120; 10th, temp., 98 deg.; pulse, 122; 11th, temp., 97·8 deg.; pulse, 128.

I regret that I have not a day-by-day record of temperature, &c.; but the marked features of the case are sufficiently indicated.

The sore-throat was a sudden slough, with well-defined edges, of the surface of one tonsil; the slough separated in the usual manner; one tonsil only was affected; there was no change from the normal state of health in any other parts of the fauces or pharynx. The fact that the patient's sister had had scarlet fever about nine weeks prior to his sore-throat, and the subsequent symptoms of joint affection and albuminuria, point to the alliance of the case to scarlet fever. After these came the well-marked brain symptoms, of a possible tubercular meningitis; and then followed—and lasting during two months—a paralytic, or most tottering gait, allying the case to the later symptoms of diphtheria.

In your issue of June 8, 1870, I published an account of some epidemics of scarlet fever, measles, and sore-throat, which occurred on board the Government emigrant ship *Hougoumont*, in voyages from Plymouth to Australia; the phenomena pointed to alliances between scarlet fever, measles, and sore-throat—*e.g.*, in the voyage of the year 1866, an epidemic of measles happened, the weekly return of cases being 2, 2, 3, 1, 3, 5, 4, 3, 3, 1, 1.

During this epidemic of measles, there evolved, in the sixth week, the first case of scarlet fever. The second and only other case of scarlet fever showed in the eleventh week. In the fifth week a case of measles occurred, which, except the copious and characteristic eruption, was much more like the sore-throat cases than it was like the other cases of measles.

I could give other instances of the evolution of epidemic diseases, such as cholera; but I have referred to these instances as presenting phenomena which point to the alliances and "form" common to different diseases, rather than to their well-marked and prevailing differences. An epidemic of sore throat coexisted with that of the measles, and one could not but be impressed with the fact of a general alliance, or series, between the measles, as showing in the very young, and the sore throat, as showing in the more adult.

The case of C. J., now reported, presents phenomena of alliances between scarlet fever, diphtheria, and sore throat, and suggests a greater "form," or wider generality, than these terms usually convey. Is not the case of C. J. one of those in which the, at present, somewhat prevailing fixity of type is least shown; whilst on the contrary, the "contained variability" of the body to epidemic rates is most shown? Is not the case of C. J., in epidemic phenomena, to be classed in what Bacon terms, "travelling instances;" and does it not fairly lead the mind away from "specific" definitions of diseases, into the domain of "comparative" disease?

# Clinical Records.

## ST. MARY'S HOSPITAL.

### *Acute Suppuration of Knee-joint—Application of Drainage Tube, Listerian Treatment being adopted—Recovery, with good Use of the Joint.*

Under the care of Mr. NORTON

(*From Notes by* Mr. MILL)

H. L., æt. 21 years, a labourer, with a strumous appearance, came to the hospital on the 23rd of May last complaining of his left knee. About a week previous to this, viz., on the 15th, when getting out of bed in the morning, he felt his left knee to be painful and swollen. He thought nothing much of it, and continued to work that day and the next, but on the 17th it was so much worse he was obliged to give up work, and on the 20th came to the hospital as an out-patient. Leeches and cold water bandages were applied, but without any effect, and on the 23rd he was admitted as an in-patient under Mr. Norton. On examination no account of any injury could be ascertained. The left leg was semi-flexed, the thigh rotated outwards; the left knee was swollen, hot, and very painful, whilst fluctuation could be felt beneath the quadriceps extensor and the ligamentum patellæ, the temperature being rather high, viz., 102·2° F. Linseed meal poultices were applied, and the leg fixed on a splint. On the 26th the knee measured sixteen inches in circumference, and the pain was severe, of a "jumping character." The temperature varied from 99 deg. F. in the morning to 102·2 deg. F. in the evening. On June 2nd the size of the knee was observed to be rather larger than previously, being now 16½ inches; tongue white and flabby; pulse 96, full and bounding; was flushed and perspiring a good deal this morning.

On the 6th Mr. Norton drew off an ounce and a-half of pus from the joint with an aspirator, which seemed to relieve the patient, as the pain was less, and he passed a better night. The knee now measured 15½ inches, and the temperature went down to normal. On the 9th, however, the joint was again 16 inches in circumference, and on the following day the temperature rose from 98 deg. F. in the morning to 101 deg. F. in the evening. Mr. Norton now determined to lay open the joint. On the 11th the patient was put under chloroform, and two incisions about ¾ in. in length were made, one on either side of the patella, leading into the joint, through which drainage tubes were passed; about two ounces of pus came away, the temperature falling to 98 deg. F. again that same evening. The operation was done under the antiseptic method. The dressings were changed on the 12th, 16th, 20th, 25th, and July 8th, on which day both tubes were taken out. After the operation the patient suffered no pain, and the temperature remained normal. On the 24th the wounds had both closed, and the dressings and splint were discontinued. Slight movement of the joint could be obtained by manipulation, and by the time he went out, on Aug. 4th, he could bend the joint sufficiently well.

# Transactions of Societies.

## SURGICAL SOCIETY OF IRELAND.

### SESSION OF 1879-80.

THE second meeting of the session was held on Friday evening, December 5, in the Albert Hall, Royal College of Surgeons, Dr. MAPOTHER, President of the College, in the chair.

Mr. B. WILLS RICHARDSON, hon. sec., read the minutes of the previous meeting.

### VESICAL CALCULUS.

Mr. WHEELER exhibited a specimen of a calculus he removed from a man aged thirty-one years. The first symptoms commenced in 1877. They however, abated, and it was not till the end of 1878 that he suffered again. He suffered intensely, and for two days after his admission he passed considerable quantities of blood. In a fortnight from his admission the stone was removed by lateral lithotomy. The stone weighed about six drachms, was one inch in length, and nearly an inch and a-half in circumference. It is a uric acid calculus, with a light phosphatic covering.

### MAMMARY TUMOUR.

Mr. CROLY exhibited a small tumour, which he designated a cystic adeno-fibroma with proliferating epithelium. He also exhibited sections of it under the microscope. The tumour was removed by him from the breast of a young lady last month. Dr. Abraham had made an examination of it with the following result:—The tumour was nearly spherical, and of a diameter of four centimetres. In consistence it was firm and elastic. It was encapsulated, the covering being easily peelable. The surface was nearly smooth, and did not show the rugosities and slight lobulation which are now apparent after four weeks in spirit. The section presented a mottled appearance and a spongy texture, the peripheral portions being whiter and denser and full of cysts, very small, but evident to the naked eye; while the central parts were looser in texture, and made up of cysts of various sizes. The intermediate connective tissue was reddish and apparently vascular. The cysts contained a thick, glairy, transparent fluid, and on cutting into the tumour a viscid juice moistened the knife, and could be scraped from the surface. It was whitish in colour, and under the microscope showed numerous large corpuscles, resembling mucous corpuscles, as well as red blood corpuscles, epithelial casts, free epithelium, and disintegrated matters. Under a low power the general structure of the growth is well seen. The acini and ducts are greatly enlarged in diameter, and the inter-alveolar tissue, simply fibrous in appearance, shows a considerable amount of hyperplasia. The cysts are evidently formed from the acini, and possibly the expansion of the latter has been caused by the pressure of the constantly increasing fluid contents. These contents seem to be in great part composed of a mucous-like liquid containing large collections of round nucleated cells of great variety of size, and with distinct nuclei (some with as many as four nuclei), also cells undergoing mucoid degeneration, and in some cases the cells are embedded in granular matter. Under the higher powers the origin of the cells can be made clear. At first sight they might be taken for leucocytes, thriving in the new medium, becoming enlarged, proliferating, and ultimately degenerating. But against this view were the facts—(1) that their nuclei did not take up the staining fluid as they ordinarily do; (2) that the whole substance of the cell became stained; (3) their irregular size; and (4) the enormous growth of some of them. Close examination showed that the collections of cells were really formed as outgrowths from the lining epithelium of the cysts, in many cases greatly resembling the lumps of germinating epithelium which are seen upon the omentum, mesentery, and on other serous membranes; in other cases, again, they formed a cauliflower-like mass, situated upon a stalk and occupying a great part of the cavity of the cyst. With care, the transition of the lining epithelial cells into the large round ones could often be made out. The inter-cystic connective tissue seemed to be in most parts of the tumour of the ordinary fibrous type, and, with the exception of its hypertrophy, showed nothing abnormal. In some places, however, it seemed to be in some degree impregnated with cellular growth, but how far this is merely inflammatory or an evidence of permanent abnormal growth, my examination has not been sufficiently extensive to determine. After looking through Paget, Cornil and Ranvier, Billroth, Laboulbene, Wilks and Moxon, and some of the smaller works on "Pathology," I have been able to find no description of a mammary tumour that will at all apply to the present specimen. By Velpeau and his followers it would, no doubt, have been called an "adenoid" tumour. Sir James Paget would have placed it among his "chronic mammaries," and Cornil and Ranvier among the fibromas. From its naked-eye appearance, perhaps, some surgeons would consider it to belong to the so-called "sero-cystic sarcomas," but as there is no evidence of any sarcomatous growth in the interstitial tissue, such a name would be incorrect. I am inclined to consider that the best name for it is a "cystic adeno-fibroma" with peculiar proliferating epithelium.

### OVARIAN TUMOURS.

Dr. **Atthill** exhibited three tumours, namely, two ovarian, and one a uterine fibrocystic tumour, which had been removed by abdominal section. Of the ovarian, one he stated did not present any points of special interest. The second was a remarkable case: the patient, a lady, had for two or three years been treated both in London and in the provinces for supposed uterine disease. She was married, but had not had any children, and had for a long time suffered intense pain at each menstrual period. He (Dr. Atthill) was of opinion that some of these attacks were in reality peritonitis. On making a careful examination he came to the conclusion that the uterus was perfectly healthy, and that she was the subject of an ovarian tumour of small size, bound down by adhesions in the left inguinal fossa. As this lady's health was rapidly failing he advised that ovariotomy be performed, and he accordingly performed it on the 1st Oct. last. On opening the peritoneum no tumour was visible, and it was only by passing the hand down into the pelvis that the correctness of the diagnosis was proved. The tumour was not much larger than a cocoa-nut, and was adherent to everything—omentum, small and large intestines, and so firmly to the pelvic wall that a good-sized piece of the cyst had to be left behind. A second cyst about the size of a kidney, attached by a pedicle to the larger cyst, was at the same time removed. This was Dr. Atthill's twenty-third operation, and was, he stated, one of the most difficult ones he had met with. Nevertheless, the patient at first made a good recovery, but, later on, symptoms of pelvic cellulitis manifested themselves. An abscess formed in the left inguinal region, and burst both into the rectum and externally through the wound. For some days an artificial anus existed. The fæcal matter soon ceased to come through the external opening; but still, even now, though the patient was able to drive out, pus was discharged both per rectum and by the wound. The uterine tumour was of much surgical and pathological interest. The patient from whom it was removed presented all the symptoms of being the subject of ovarian disease. There was a large movable tumour in which fluctuation could be distinctly felt, and it could be separated from the uterus, the only point which made him (Dr. Atthill) doubtful, being that menstruation was profuse. This circumstance induced him to chloroform the patient, and to examine her while under its influence, and satisfying himself that the tumour could be separated completely from the uterus, he operated, believing it to be ovarian. It proved, however, to be a fibro-cystic tumour, attached to the uterus by a short but slender pedicle, and he did not see how this tumour could have been distinguished, prior to the operation, from an ovarian cyst. On making an incision into it, it proved to contain a quantity of glairy fluid. The tumour was removed, but there was a good deal of hæmorrhage, and the patient sank and died within twenty-four hours.

### CARIES OF CLAVICLE.

Mr. **Wheeler** exhibited a specimen of an entire right clavicle, save a small portion of the acromial end, removed by him from a female patient thirty years old. There were two openings, one at centre of bone, the other nearer sternal end, from which large quantities of pus exuded, and through which the bone could be felt. Her own account was that in the March previous a pain struck her in the shoulder when carrying a basket. In two or three days after the parts about her shoulder and clavicle began to swell; the pain was intense. The swelling broke about a month from its commencement, and there was a discharge of about two quarts of pus. A considerable discharge continued, which weakened her much, she lost flesh, had sleepless nights, and perspired copiously. He believed Mott was the first to remove the clavicle in 1828. His operation took four hours to perform, and forty vessels were ligatured. The woman under notice left hospital on the 2nd August perfectly well.

### MAMMARY TUMOUR (SCIRRHUS).

Mr. **Wheeler** exhibited an encapsuled scirrhus tumour of the breast.

Mr. **Stokes**

### ON A CASE OF LITHOLAPAXY, OR LITHOTRITY AT A SINGLE SITTING

which will be found on page 1.

Mr. **Porter**.—I do not think any surgeon who has ever performed the operation of lithotrity can for a moment doubt the great improvement suggested by Bigelow. The sooner we get the fragments of a broken calculus out of the bladder the better; and there is no doubt that his instrument accomplishes the object in a most efficient manner. With respect to Sir Henry Thompson's instrument, it appears to me that if a short portion of elastic tubing were placed between the brass shaft of the instrument and the catheter it would be a great improvement. I cannot help thinking from my experience of working with Clover's apparatus that there is a great deal of unnecessary shaking of the instrument in the bladder owing to its fixed condition. Mr. Stokes's case has been most interesting, seeing the very large-size fragments removed through the straight instruments. I have never myself performed Bigelow's operation as he recommends; but when the instrument first came into Dublin I was crushing a stone in a gentleman's bladder, and I removed some fragments with Bigelow's instrument. My experience is that the large calibre of the catheter seemed to give the patient a great deal of pain. He was not put under ether or chloroform. It is of great importance to get an instrument of that calibre in, if you can do it with facility, and the straight shape of the instrument facilitates the fragments being carried out.

Dr. **Cruise**.—I beg permission to make a few observations on this highly interesting and important communication we have just had from Professor Stokes. In the first place I think this Society will agree with me in feeling very thankful to him for his exhaustive paper, and for opening the discussion by the record of the first case of litholapaxy, as modified by Bigelow, which has been performed in Ireland. The principal interest of the few words I will say is that they will go to prove that the Irish School of Surgery has not been behindhand in working out the great problem of evacuating the crushed calculus as rapidly as possible. Professor Stokes has already detailed to you the earliest efforts in this direction by the late Sir Philip Crampton, later by Mr. Clover of London, and finally by Professor Bigelow. As regards the labours of the latter surgeon, I think it is not easy to overrate the importance of his work, and the influence it has had in determining the present views of the profession on this subject. Looking to the past we find there were two distinct schools of lithotrity. One school recommended and practised the immediate removal of as much of the fragments as possible. This view was principally represented by the late Sir William Fergusson, who always endeavoured to extract as much as possible in the blades of the lithotrite—a proceeding full of the danger of laceration of the urethra. Reliquet, too, in his able work, published in 1871, evidently leans to immediate evacuation as a rule, and speaks in favourable terms of Clover's instrument. During the latter years of his practice Civiale, the great Father of Lithotrity, leaned to the same idea. I have seen him, in the year 1858, after crushing, use a large catheter and powerful syringe, with the aid of which he, in my presence, at the Hôpital Necker, washed out the bladder, and inviting it to contract by ample injections, evacuated the fragments wholesale. The other school, represented by the most eminent living lithotritist, Sir Henry Thompsom, rather advocated the perfect crushing of the stone, and dependence on Nature to expel the débris with the urine. This was his teaching up to the publication of the second edition of his invaluable work on lithotrity. However, slowly but steadily, the necessity of quickly ridding the bladder of the offending matter became a manifest truth, and in 1876 we find Sir Henry Thompson in his admirable lectures on "Diseases of the Urinary Organs" (fourth edition, pages 193 to 201), with characteristic love of progress, urging quick repetitions of the crushings, under anæsthesia, and the systematic use of Clover's apparatus when there is any difficulty in passing water. Next we arrive at Bigelow's essay, published in 1878, in which he boldly tells us to crush the stone freely, and with huge evacuating catheter to complete the removal in one operation, the patient being under ether. Finally, in the present year, we find Sir Henry Thompson rapidly tending towards a similar line of practice, whenever at all prudent (see fifth edition of his Lectures, chapter xiii). To him we are, moreover, recently indebted for a very useful form of Clover's apirator, in some respects, I think, preferable to Bigelow's modification of that invaluable instrument. Gentlemen, let me remind you that all the time this progress has been working out in lithotrity the Dublin School has not been idle. The first idea of sucking out the fragments by atmospheric pressure was Crampton's. The really practical application of the idea was Clover's, for all other instruments are mere modifications of his. I first saw Clover's apparatus used by Mr. Porter some thirteen years ago, in the case of an old gentleman with feeble bladder, who was unable to expel the fragments. Clover's apparatus removed much, and Nature the rest. He was perfectly cured of the stone, but died some years since from heart disease. Since that time I have constantly used Clover's instrument, and derived invaluable help from it. In most of my cases I was associated with Mr. Porter, and assisted him in many of his, and I was strongly influenced by his constant teaching of the necessity of getting away the fragments as soon as possible in order to avoid cystitis and fever. Several years ago I suggested to him the use of two lithotrites in operating, one being used for crushing, while an assistant removed the débris from the one recently withdrawn loaded, and certainly by that device we avoided delay and abbreviated the operation. The most triumphant success I experienced with Clover's apparatus was in a case to which I now call your special attention :—In February, 1877, I was consulted by a gentleman from the Co. Meath, aged abcut seventy. For many years he had suffered from prostatic disease and retention of urine, requiring the use of the catheter every five or six hours. From this necessity he had become an expert catheterist, and suffered no pain to signify until a few months previous to my seeing him. For that period he complained of excessive and increasing urinary irritation, requiring the constant use of the instrument, and the operation gave great pain, and the urine was loaded with mucus and pus. I suspected a phosphatic calculus, and on sounding found what I believed to be one. I arranged that he should come to town. March 20th I crushed the stone, and found from the débris in the lithotrite that it was phosphatic, as I suspected. I provided him with a full-sized catheter, with a large orifice, and anxiously watched for the discharge of fragments. Very little came, and much irritation and fever followed the crushing, so that my patient was rather worse than otherwise. Mr. Porter saw him in consultation with me. In vain we tried diluents, sedatives, rest, poulticing, and hip baths. Finally, on the 31st of March, we decided to make a vigorous effort to get rid of the stone at once. Accordingly I crushed it thoroughly with a small lithotrite, made for me by Charriere, of Paris, and forthwith pumped out the fragments with Clover's apparatus (the instrument and the débris of the stone were exhibited). The operation lasted far less than half-an-hour, and was borne with the utmost fortitude by the patient, who took no anæsthetic. The relief was almost magical, and on the 5th of April, six days after the operation, the patient returned home. Since then he has remained perfectly well and free from annoyance, except that due to the necessity of using his catheter regularly. The special interest of this case of rapid evacuation of the calculous débris lies in the fact that it dates March 31, 1877, about eight months prior to Bigelow's paper, in which he advocates such a practice. For myself, I confess I don't like such gigantic evacuating catheters as Bigelow uses. I prefer No. 16, English gauge, both of the straight and curved variety. I am inclined to fear that with the very large instruments we run an unnecessary risk of shock, and of abrasion of the mucous membrane of the urinary passages, which latter I believe to be a fertile cause of urinary absorption and fever, sometimes ending in pyæmia. I have been influenced in making these remarks mainly by a desire to show that our Irish School has not been idle in this very important domain of practical surgery.

Mr. J. K. **Barton** asked Mr. Stokes to state the position in which the patient was placed in order to facilitate the passage of the fragments. He himself had lately had a case of lithotrity in which he employed Sir Henry Thompson's instrument to evacuate the bladder, not at one sitting, but after several sittings, and he had been greatly disappointed in its use. He used No. 14 catheter, the urethra being rather small, but it did not draw out the fragments in the free way he expected from the reading of Sir Henry Thompson's and Bigelow's papers. In fact very scanty relief was obtained, and very much larger evacuation was afforded by the patient's own efforts. He used it on three different occasions, and in all he was disappointed with its action. He did not find any injury done by it, but he quite agreed in Mr. Porter's observations that there was a certain degree of shock in using the instrument on account of its fixity. His patient was not under the influence of ether, and although quite free from inflammation of the bladder, the operation was unpleasant. The point of his observations was that he was disappointed in the amount of débris withdrawn, although he made the fluid pass in and out frequently, following Sir Henry Thompson's advice as regards the breathing of the patient, to let it flow by inspiration and expiration.

Dr. **Atthill**.—I have no personal experience in the treatment of calculus as it occurs in the male ; but I have had several females in whom it occurred. Stone in the bladder is, of course, a much less serious affliction in a woman than in a man ; and, as you are all aware, it is generally treated by pre-dilatation of the urethra. Nevertheless, one of my patients within the last year died after this method of treating it. I therefore think that the operation brought before the Society by Mr. Stokes is calculated to be a great boon. It is especially suited to women ; because, without any difficulty whatsoever, a very large-sized catheter can be passed into the female bladder. Mr. Stokes has alluded to a case in which he was kind enough to assist me last summer. The patient was a lady, aged about fifty, and this was unfortunately her second operation, inasmuch as I performed ovariotomy on her a few months before. A stone formed in the bladder, subsequently caused a great deal of irritation, and in the month of August last Mr. Stokes assisted me to remove it. We dilated the urethra rapidly, introduced one of the larger size tubes, and in the course of half-an-hour or so removed the entire calculus. In about three days she recovered full command of the bladder, and has enjoyed a great deal of comfort ever since.

Professor **Bennett**.—Some years ago, before the death of Sir William Fergusson, I had an opportunity of seeing him twice on one occasion in King's College Hospital perform the operation in the case of two rather oldish men, who were under chloroform. He seized the stone with a large lithotrite to break it as freely as he could, and then with a smaller instrument he extracted the fragments then and there. Educated with the ideas handed down by Crampton, it was a fearful sight to see his treatment of the urethra, because he insisted that there was only a necessity to bring the fragments of stone, no matter how large, into the urethra, and once you pass the neck of the bladder, treat the urethra with contempt. I saw him pull it clean out, repeating the process many times. What the condition of the urethra was in afterwards I do not know. However, going round King's College Hospital not long ago, I asked one of the surgeons whether Sir William Ferguson's practice was still followed, and he said not—they saw reasons to discontinue it. This is evidence, at all events, that the active school often treat the urethra with a little extra violence.

Mr. **Stokes**.—I am gratified that my remarks have elicited so much interesting and valuable matter from the various members of the Society who have had experience of the important operation of lithotrity. In reference to Mr. Porter's suggestion that a short portion of elastic tubing should be placed between the aspirator and the cathether, it might possibly be an advantage ; but if so placed, it should be a very small portion ; for there is a great deal in what Sir Henry Thompson has said on the importance of direct communication between the aspirator and the catheter in facilitating the evacuation of the calculous débris. The shorter the journey it has to travel the better—the more power the surgeon has over the contents of the bladder. In operating on persons who are not under the influence of an anæsthetic, it would be an advantage and prevent the objection Teevan has raised to Clover's instrument, namely, the jerking of the evacuating catheter in the urethra and the bladder. As to the pain that it caused, I have no doubt that would be experienced in cases where the patient was not brought under the influence of an anæsthetic. But in all cases, unless there is some very strong contrary indication, the employment of some anæsthetic is desirable, as then we need not be terrified at the prospect of any pain that may be caused by the introduction of the evacuating catheter. As regards Dr. Cruise's division of the two schools of lithotritists into those that made it their object to evacuate as much as possible of the débris at once, among whom he mentioned Civiale and Fergusson, and also the school of quietists, among whom he ranked Sir Henry Thompson, it is right to observe, although Sir Henry Thompson may have been originally of that school, lately he had apparently come round to the other school, and now his great object is to evacuate as much as possible and at once. So that he can no longer be called one of the quietists of lithotritists; because in a paper, published in the *British Medical Journal* last August, he dwells on the importance of at once removing the débris. What Dr. Cruise mentioned about the employment of several lithotrites has been a very good method prior to the introduction of Bigelow's large evacuating catheter. When you have not got a large catheter the introduction and removal of the calculus with lithotrites is doubtless an excellent plan; and having regard to the pre-Bigelow period great credit is due to this simple method of removing as much as possible of the débris. I think this is no longer necessary, and the object of all surgeons performing the operation should be to have as little introduction of instruments as possible. I am quite aware that Mr. Porter has laid down the dictum on more than one occasion to remove as much as possible of the stone; and in this way it is interesting that he foreshadowed the idea that has been realised by Bigelow and Sir Henry Thompson. Dr. Cruise has raised an objection to the large size of the instrument; but when the patient is properly under the influence of an anæsthetic there is little or no shock experienced by the passage of the instrument. In reference to Dr. Barton's observation, I have merely to say that the patient being under the influence of ether, was placed in the horizontal position, which is the position generally adopted in the performance of the operation. I am sorry to hear he was disappointed with Sir Henry Thompson's instrument, because in a theoretical point of view I would say it is admirable. My own experience is, up to this time, confined to Bigelow's, and I cannot, therefore, from my own experience, speak of the value of Sir Henry Thompson's aspirator. It was important to learn that Dr. Atthill considers this method is likely to be of such use in dealing with calculi occurring in the female bladder. Lastly, I would allude to what Professor Bennett has said in reference to Sir William Fergusson's method of removing calculous débris. It was new to me to learn that the eminent surgeon he mentioned ever employed force in removing the débris by means of large lithotrites, and although the idea of removing as much as possible of the calculus at the time of the operation is doubtless a good one, still the practice alluded to is one which hardly commends itself to surgeons of the present day.

◆

Sir Joseph Napier has resigned the Vice-Chancellorship of Trinity College, Dublin, and it is expected that he will be succeeded by Mr. J. T. Ball, Lord Chancellor of Ireland.

---

In the principal foreign cities the rates of mortality, according to the most recent weekly returns were—in Calcutta 37, Bombay 38, Madras 34; Paris 32; Geneva 21; Brussels 38; Amsterdam 31, Rotterdam 34, The Hague 34; Copenhagen 30; Stockholm 23; Christiania 19; St. Petersburgh 38; Berlin 25, Hamburg 29, Dresden 19, Breslau 25, Munich 27; Vienna 26; Buda-Pesth 29; Turin 29, Alexandria 40; New York 26 per 1,000 of the population. Small-pox caused 27, and typhoid fever 21 deaths in Paris.

## THE REPORT ON THE EDUCATION OF THE GENERAL PRACTITIONER.

The present unsatisfactory condition of the young man who has just become possessed of his diploma is such that the Metropolitan Branch of the British Medical Association some time ago appointed a committee to inquire into the matter. This committee consisted of teachers, as Drs. Andrew Clark, Pye-Smith, F. Roberts, Messrs. Savory, John Wood, Bryant, Gant, and others, while the general practitioner was represented by Mr. Sibley, Dr. Ford Anderson, Dr. Brodie Sewill, and others. These names are those of good representative men; and the conclusions of such a committee must carry weight with them to every reader of the report. This committee sent questions to numerous medical men, metropolitan and provincial teachers, and also general practitioners, members of the branch. In response, they received 400 and odd replies. The first question put was this: "Is it desirable that intending medical students should pass an examination in the elements of botany, physics, and inorganic chemistry *prior to admission* to the regular medical curriculum, and that these subjects should form part of their 'preliminary general education and examination?'" To this question 90 per cent. of the past and present teachers, and 96 per cent. of the general practitioners returned an affirmative answer. Certainly such examination is very desirable in the face of the fact that a large percentage of the youths who commence a medical career fall out of the ranks, and, sooner or later, adopt some other occupation. A course of teaching on the above subjects would make a lad all the fitter to profit by his lectures and his other departments of medical study. He would know the advantages of a hollow bone, and would take an interest in the insertion and origin of muscles from the consideration of their action and function; while he would be rid of the labour of remembering lots of series of acids among his other study, up to the time of his primary professional examination. Such like lore is an incubus on a man's memory; but once acquired, enough would remain for all intelligent study of organic chemistry, and especially the chemistry of digestion and assimilation, of which far too little is at present taught. If such an addition as is proposed were made to the present existing preliminary examination, the class of men entering the ranks of medical students would be much improved. Whether such a scheme is feasible or not we are not called upon to decide; time will show.

The second question is:—"Is it desirable that a certain period, previous to admission to a medical school, should be spent with a general practitioner in the form of 'articled pupilage?'" This was subdivided further into—*a.* "If so, when and how long?" and *b.* "And which of the subjects mentioned in Question I. should form a part of this preliminary training? or are there any others?" As might be expected, there was a marked diversity of opinion in the answers returned to this question. Seventy-four per cent. of the general practitioners held that "there is a want in the education of medical students as regards teaching in the art of prescribing." They stated that the young medical man, when called upon to take charge of a practice, shows little familiarity with the work to be done, bringing discredit upon himself and his employer, and exciting dissatisfaction amongst the patients, club and private. Not only that, but many discover the work is not what they anticipated, and so become discontented themselves, and regret that they have ever entered the profession. The general practitioners contended that an experience as a pupil would alone correct this. On the other hand, 70 per cent. of the teachers were of opinion that a return to the system of apprenticeship in any form would be a serious error, which they could find it impossible to sanction. They assert it unfits the lads for systematic work, they are self-satisfied, and supercilious on the strength of their limited acquaintance with practical work; and that the little they have learnt is a hindrance rather than an advantage to them in their studies. That this may be so in a number of instances is probable; but in our experience we have known these youths to have exhibited a a strongly developed tendency to seize readily upon the different subjects of their study with a keen eye to what was of practical use at the bedside. They have some idea of what it is they want to know for future use, and, therefore, how to select and store. That some such means of becoming familiar with what is required for private patients, is illustrated by what we are about to say. Lately, we asked separately two qualified young men—one lately a house-physician at a teaching hospital of repute, another house-physician at a non-teaching hospital—what they would do, and what they would say to a portly gentleman of 60, who was able to sit up three hours daily, and recovering from a smart attack of bronchitis; and with a sharp old lady, his wife or cousin, reading the newspaper to him. Neither recognised the importance of this last factor in the very least. What each would say was very little; and betrayed utter ignorance of those routine questions and directions which experience among a good-class of patients demonstrates to be so essential to success; but each was very positive that he "would have up his night-shirt and listen to both bases at the back." This may be the correct thing with an hospital patient; but in our experience it would not work well with a portly old gentleman in a roomy arm chair, wrapped voluminously in flannels; and the sharp old lady would certainly have her views about the young doctor's experience. Their laudable desire to know the condition of the lungs "at the back" was creditable; but lung-congestion of the kind they dread is a much more marked feature in hospital than in private practice. The same end could be attained in a manner quite as valuable practically, by counting the respirations and the pulse, and noting the proportion. This would meet the views of the patient and his friends much more satisfactorily; but then the young medico, as matters now are, has to learn to unlearn much of his hospital teaching, and acquire a knowledge of what is needed in private practice as he can, and usually with much painful experience. Young doctors rarely realise that what they think about their patients is not the whole matter; and commonly forget to calculate what the patients (and their friends) are thinking about them. But, the latter factor they will find, is not unimportant. The third question is:—"Is it desirable that the age of eighteen years should be attained before a student enters the regular medical curriculum, and that the age of twenty-two years be completed before he is permitted to receive a qualification to practice?" To this 89 per cent. of the teachers, and 97 per cent. of the general practitioners returned an affirmative answer on both heads. It was granted that in very exceptional cases a bright industrious youth might be equal to commence medical study at seventeen, and pass at twenty-two; but then rules must be made for the overwhelming majority, not for the rare exception.

The fourth question is:—"Do you approve of the introduction of an examination in elementary anatomy and physiology at the end of the first year of medical studies?" To this 79 per cent. of the general practitioners, and but 58 per cent. of the teachers, answered affirmatively. It was contended that some such examination would help to weed out the idle men, that large class who never pursue their medical studies to the successful end of a license to practise. On the other hand no less than 42 per cent. of the teachers opposed any such test being applied. They thought it would press too severely on provincial students, which it would, doubtless; and that it would keep up a state of nerve tension already harassing to many men.

Granting this, "much of the imperfection of the training of our students depends on their wasting the first year of their hospital course, trusting to their power of cramming up for their examination in the second year." That such is the mental attitude of many first year's men may not be denied; and that, too, of the idle men of whom it is so desirable to be rid. The careless, idle, if not dissipated, disrespectful young—well, we will not say ruffians, but unlicked cubs, of which some are to be found amidst the first year's men at any large medical school, are a simple nuisance; and then, again, how can these youthful procrastinators be sure that they will be able to cram successfully in their second year. In our experience not a few of this style of men defer their study till the Christmas vacation of the second winter is passed, and then discover that they have not got the power with which they so boastfully and vain-gloriously accredited themselves. For this class of man, who does not know what a state of nerve tension is, such early examination would be very desirable.

The committee decided that some such public examination should be held, and that those who fail to pass it, whether from idleness or carelessness, should have a limited time to regain the lost ground; and that if then they still be found wanting, means should be taken to rusticate them till such time as they could satisfy the school authorities that they had commenced to work in earnest. This would be an excellent discipline for the class of youth just alluded to above, and would probably bring each young idler to his senses, such as they are, and would diminish the high estimate which he places upon his own abilities—when the time comes that he chooses to manifest them! It is possible, too, to hold the view that by spreading the examinations over a youth's course of medical study, the nerve tension of those who experience it would be lessened, and the intensity of it avoided to some extent; and that it is felt intensely at the time of their present examinations some sad recent events make us only too painfully aware. And this is shown, too, especially at the first primary examination: so that it does seem desirable to take some part of the examination at an earlier date, and thus to relieve the anxious student by dividing his load. In those sadder cases where the youth is industrious, but lacks the ability to pass, it would only be kind to demonstrate this to himself first, and then to his friends, to save him from futile toil, to save them throwing away more money over an unattainable object. We will refer to the rest of the questions in a future number.

## RETREATS FOR HABITUAL DRUNKARDS.

Dr. Cameron's much-needed Act for the restraint and cure of habitual drunkards came into operation on the first day of the New Year, and already we have had many inquiries as to whether many retreats are likely to be established under its authority, from which we judge that considerable demand for such institutions has long existed. We may with advantage recapitulate the terms of the Act with reference to this matter.

By its 6th section the "local authority" is empowered to grant licenses for the opening of a retreat. The local authority is, usually, the Justices of the Peace. The sections run as follows:—

6. The local authority may, subject to any conditions which such local authority shall deem fit, grant to any person, or to two or more persons jointly, a license for any period not exceeding thirteen months, to keep a retreat; and may from time to time revoke or renew such license. One at least of the persons to whom a license is granted shall reside in the retreat, and be responsible for its management. A duly qualified medical man shall be employed as medical attendant of such retreat, provided that when the name of the licensee shall be on the Medical Register he may himself act as such attendant.

7. No license shall be given to any person who is licensed to keep a house for the reception of lunatics.

10. Any habitual drunkard desirous of being admitted into a retreat may make application in writing to the licensee of a retreat for admission into such retreat, and shall state the time during which such applicant undertakes to remain in such retreat. Such application shall be accompanied by the statutory declaration of two persons to the effect that the applicant is an habitual drunkard within the meaning of this Act.

Such applicant, after his admission and reception into such retreat, unless discharged or authorised by license as hereinafter provided, shall not be entitled to leave such retreat till the expiration of the term mentioned in his application, and such applicant may be detained therein till the expiration of such term; provided that such term shall not exceed the period of twelve calendar months.

As we have said, we have reason to believe that there is need for the establishment of one or more retreats in Ireland, where no such institution has ever existed, and that it would probably prove a remunerative venture; but, as will be seen by reference to the seventh section, no proprietor of a private lunatic asylum can also be proprietor of a retreat.

# Notes on Current Topics.

## Sir Dominic Corrigan.

We regret to announce the very serious illness of Sir Dominic Corrigan, representative of the Queen's University in the General Medical Council, who has for some days been confined to bed, and in a condition to cause much alarm. Sir Dominic Corrigan has been for years a sufferer from gout, and recently had become so feeble as to be scarcely able to move about.

## A Dilemma for the Adulterators.

The *Analyst* observes that in the English Court of Queen's Bench, a case was recently decided which "distinctly marks a new departure" in the law of adulteration. A police-constable asked for "half-a-pound of coffee," which was duly taken from a canister and delivered across the counter, while the sum of 9d. was charged and paid, such being the price of good coffee at 1s. 6d. per lb. On the constable stating that the article was for analysis, the proprietor came forward, and, while the *prior to admission* to the regular medical curriculum, and that these subjects should form part of their 'preliminary general education and examination?'" To this question 90 per cent. of the past and present teachers, and 96 per cent. of the general practitioners returned an affirmative answer. Certainly such examination is very desirable in the face of the fact that a large percentage of the youths who commence a medical career fall out of the ranks, and, sooner or later, adopt some other occupation. A course of teaching on the above subjects would make a lad all the fitter to profit by his lectures and his other departments of medical study. He would know the advantages of a hollow bone, and would take an interest in the insertion and origin of muscles from the consideration of their action and function; while he would be rid of the labour of remembering lots of series of acids among his other study, up to the time of his primary professional examination. Such like lore is an incubus on a man's memory; but once acquired, enough would remain for all intelligent study of organic chemistry, and especially the chemistry of digestion and assimilation, of which far too little is at present taught. If such an addition as is proposed were made to the present existing preliminary examination, the class of men entering the ranks of medical students would be much improved. Whether such a scheme is feasible or not we are not called upon to decide; time will show.

The second question is:—"Is it desirable that a certain period, previous to admission to a medical school, should be spent with a general practitioner in the form of 'articled pupilage?'" This was subdivided further into—*a.* "If so, when and how long?" and *b.* "And which of the subjects mentioned in Question I. should form a part of this preliminary training? or are there any others?" As might be expected, there was a marked diversity of opinion in the answers returned to this question. Seventy-four per cent. of the general practitioners held that "there is a want in the education of medical students as regards teaching in the art of prescribing." They stated that the young medical man, when called upon to take charge of a practice, shows little familiarity with the work to be done, bringing discredit upon himself and his employer, and exciting dissatisfaction amongst the patients, club and private. Not only that, but many discover the work is not what they anticipated, and so become discontented themselves, and regret that they have ever entered the profession. The general practitioners contended that an experience as a pupil would alone correct this. On the other hand, 70 per cent. of the teachers were of opinion that a return to the system of apprenticeship in any form would be a serious error, which they could find it impossible to sanction. They assert it unfits the lads for systematic work, they are self-satisfied, and supercilious on the strength of their limited acquaintance with practical work; and that the little they have learnt is a hindrance rather than an advantage to them in their studies. That this may be so in a number of instances is probable; but in our experience we have known these youths to have exhibited a a strongly developed tendency to seize readily upon the different subjects of their study with a keen eye to what was of practical use at the bedside. They have some idea of what it is they want to know for future use, and, therefore, how to select and store. That some such means of becoming familiar with what is required for private patients, is illustrated by what we are about to say. Lately, we asked separately two qualified young men—one lately a house-physician at a teaching hospital of repute, another house-physician at a non-teaching hospital—what they would do, and what they would say to a portly gentleman of 60, who was able to sit up three hours daily, and recovering from a smart attack of bronchitis; and with a sharp old lady, his wife or cousin, reading the newspaper to him. Neither recognised the importance of this last factor in the very least. What each would say was very little; and betrayed utter ignorance of those routine questions and directions which experience among a good-class of patients demonstrates to be so essential to success; but each was very positive that he "would have up his nightshirt and listen to both bases at the back." This may be the correct thing with an hospital patient; but in our experience it would not work well with a portly old gentleman in a roomy arm chair, wrapped voluminously in flannels; and the sharp old lady would certainly have her views about the young doctor's experience. Their laudable desire to know the condition of the lungs "at the back" was creditable; but lung-congestion of the kind they dread is a much more marked feature in hospital than in private practice. The same end could be attained in a manner quite as valuable practically, by counting the respirations and the pulse, and noting the proportion. This would meet the views of the patient and his friends much more satisfactorily; but then the young medico, as matters now are, has to learn to unlearn much of his hospital teaching, and acquire a knowledge of what is needed in private practice as he can, and usually with much painful experience. Young doctors rarely realise that what they think about their patients is not the whole matter; and commonly forget to calculate what the patients (and their friends) are thinking about them. But, the latter factor they will find, is not unimportant. The third question is:—"Is it desirable that the age of eighteen years should be attained before a student enters the regular medical curriculum, and that the age of twenty-two years be completed before he is permitted to receive a qualification to practice?" To this 89 per cent. of the teachers, and 97 per cent. of the general practitioners returned an affirmative answer on both heads. It was granted that in very exceptional cases a bright industrious youth might be equal to commence medical study at seventeen, and pass at twenty-two; but then rules must be made for the overwhelming majority, not for the rare exception.

The fourth question is:—"Do you approve of the introduction of an examination in elementary anatomy and physiology at the end of the first year of medical studies?" To this 79 per cent. of the general practitioners, and but 58 per cent. of the teachers, answered affirmatively. It was contended that some such examination would help to weed out the idle men, that large class who never pursue their medical studies to the successful end of a license to practise. On the other hand no less than 42 per cent. of the teachers opposed any such test being applied. They thought it would press too severely on provincial students, which it would, doubtless; and that it would keep up a state of nerve tension already harassing to many men.

Granting this, "much of the imperfection of the training of our students depends on their wasting the first year of their hospital course, trusting to their power of cramming up for their examination in the second year." That such is the mental attitude of many first year's men may not be denied; and that, too, of the idle men of whom it is so desirable to be rid. The careless, idle, if not dissipated, disrespectful young—well, we will not say ruffians, but unlicked cubs, of which some are to be found amidst the first year's men at any large medical school, are a simple nuisance; and then, again, how can these youthful procrastinators be sure that they will be able to cram successfully in their second year. ## RETREATS FOR HABITUAL DRUNKARDS.

Dr. Cameron's much-needed Act for the restraint and cure of habitual drunkards came into operation on the first day of the New Year, and already we have had many inquiries as to whether many retreats are likely to be established under its authority, from which we judge that considerable demand for such institutions has long existed. We may with advantage recapitulate the terms of the Act with reference to this matter.

By its 6th section the "local authority" is empowered to grant licenses for the opening of a retreat. The local authority is, usually, the Justices of the Peace. The sections run as follows:—

6. The local authority may, subject to any conditions which such local authority shall deem fit, grant to any person, or to two or more persons jointly, a license for any period not exceeding thirteen months, to keep a retreat; and may from time to time revoke or renew such license. One at least of the persons to whom a license is granted shall reside in the retreat, and be responsible for its management. A duly qualified medical man shall be employed as medical attendant of such retreat, provided that when the name of the licensee shall be on the Medical Register he may himself act as such attendant.

7. No license shall be given to any person who is licensed to keep a house for the reception of lunatics.

10. Any habitual drunkard desirous of being admitted into a retreat may make application in writing to the licensee of a retreat for admission into such retreat, and shall state the time during which such applicant undertakes to remain in such retreat. Such application shall be accompanied by the statutory declaration of two persons to the effect that the applicant is an habitual drunkard within the meaning of this Act.

Such applicant, after his admission and reception into such retreat, unless discharged or authorised by license as hereinafter provided, shall not be entitled to leave such retreat till the expiration of the term mentioned in his application, and such applicant may be detained therein till the expiration of such term; provided that such term shall not exceed the period of twelve calendar months.

As we have said, we have reason to believe that there is need for the establishment of one or more retreats in Ireland, where no such institution has ever existed, and that it would probably prove a remunerative venture; but, as will be seen by reference to the seventh section, no proprietor of a private lunatic asylum can also be proprietor of a retreat.

# Notes on Current Topics.

## Sir Dominic Corrigan.

We regret to announce the very serious illness of Sir Dominic Corrigan, representative of the Queen's University in the General Medical Council, who has for some days been confined to bed, and in a condition to cause much alarm. Sir Dominic Corrigan has been for years a sufferer from gout, and recently had become so feeble as to be scarcely able to move about.

## A Dilemma for the Adulterators.

The *Analyst* observes that in the English Court of Queen's Bench, a case was recently decided which "distinctly marks a new departure" in the law of adulteration. A police-constable asked for "half-a-pound of coffee," which was duly taken from a canister and delivered across the counter, while the sum of 9d. was charged and paid, such being the price of good coffee at 1s. 6d. per lb. On the constable stating that the article was for analysis, the proprietor came forward, and, while the packet was still on the counter, called the constable's attention to the fact that it was a mixture, as indicated by the words printed on the paper, "This is sold as a mixture of chicory and coffee." On analysis the article was found to contain coffee sixty parts, and chicory forty parts. Defendant relied on the 8th section of the Act, providing that a person selling a mixture may label the same, and so be exempt from punishment. The magistrates, however, considered that, seeing the purchaser asked for coffee and paid the price of coffee, he should be protected against being served with a mixture which he did not desire, and they therefore convicted the defendant, who now appealed. The Court, after hearing the appealing counsel, and without requiring any reply, unanimously upheld the conviction.

## Waste of Food.

At a meeting held the other evening, in the National School, Loughton, Mr. Buckmaster delivered a lecture, in the course of which he said it was very natural and proper at this time of the year, especially for those who were blessed with abundance, to think of the poor, and a very popular form of charity at this time of the year was a dinner. He had already pointed out the waste which frequently attended these dinners, which were not dinners in the ordinary sense, but downright gluttony. This Christmas, in a well-known refuge, which was constantly appealing for help, each child was fed or supplied with 4½lb. of solid food—beef, pudding, and potatoes, no mention was made of bread; in another 4¼lb.; some aged poor had 4¼lb. and a pint of beer, making 5¼lb.; in a well known hospital near 5½lb. In an infirmary, where one might reasonably suppose the recipients were not in robust health, each patient was provided with 3¾lbs. of solid food and a pint of porter. In the opinion of the lecturer every dinner given to persons who really want one which exceeds sixpence each is waste, and if the price were kept within this limit the number of applicants would be greatly diminished. We can hardly concur with the lecturer in his estimate of the price of a comfortable and sufficiently nutritive dinner, but we fully accept his view that the gormandising by which the great Christian anniversary is honoured is often nothing better than the swinish gratification of depraved appetite. It is, in fact, nothing better than hard drinking, save that its ill effects are not so immediate, so obvious, or so generally hurtful.

## Infant Prescribers.

At an inquest held at the East End of London on Saturday last, another sad instance came to light of the danger to life the public in poor neighbourhoods run through the incompetence or neglect of "counter prescribers." The inquiry had reference to the death of a child named Lilian Holt, aged five. Frederick Hughes, a lad of thirteen, stated that he was employed by Dr. Ayres Moore, at 53 St. Leonard's Road, Shoreditch. A girl called on Tuesday and stated that she wanted a powder for a child. Witness took a bottle from a shelf and handed it to the assistant's wife, who after placing some of the contents in a paper gave it to the girl and charged her twopence for it. Mr. F. M. Henbeck, L.S.A., assistant to Dr. Moore, said that at the time of the sale of the powder he was out visiting. The amount of morphia administered was six grains. Witness had repeatedly told Hughes not to serve in the shop. The jury returned a verdict of Death by misadventure, at the same time expressing their opinion that there had been gross neglect on the part of those whose duty it was to attend to the management of the drugs.

We quite agree with the opinion of the jury, and think that had they gone a little farther and made some one answerable for manslaughter, it might have had a wholesome effect. Here we have the terrible picture before us of a boy of thirteen and a woman unversed in medicine toying with the lives of poor people, the one prescribing morphia, the other dispensing the drug. And this according to the assistant's own admission, was not the first time by many that this boy had played the part of doctor in the same shop. Surely such an iniquity should not be allowed to pass with no other record than the easily forgotten verdict of "death by misadventure."

## The Parkes Museum of Hygiene.

On Saturday last, a series of practical demonstrations of the uses of sanitary appliances was commenced in the museum which has been recently founded to perpetuate the memory of the late Dr. Parkes. Mr. Judge (the curator) stated that Professor Corfield would deliver the first and second address on the subject of "House Drainage," and "Ventilation, Light, and Warmth;" which would be followed by lectures on "Food," by Dr. Vivian Poore, and on the "Hospital and Sick Room," by Dr. J. C. Steele. These demonstrations are intended specially for working men, and will take place on alternate Saturdays. At the initiatory lecture, Professor Corfield first drew attention to the various kinds of drain pipes in use in houses. Those pipes, instead of being made of brick, ordinary tiles, or other pervious material, as was generally the case, should be composed of some impervious material, so that the foul water could not soak through. They should be made of glazed stoneware, and should be jointed in a very different manner to that now generally adopted. He discouraged the use of cement for joints, and described Stanford's patent of gutta percha rims to the ends of the pipes, which, by means of a little grease, could be connected and rendered water-tight. Instead of bell traps for yards, syphon gulleys should be used, and after referring to various road gulleys and Rogerfield's flush tanks, Professor Corfield described some traps intended to disconnect the soil pipes and sinks from the house sewers, which it was important should be used, provided there was an air inlet from the drain. A number of examples of defective plumbing, chiefly associated with the old D trap, were next given, and the professor strongly discouraged the use of those traps, which were contrivances which caught a great deal of solid matter, and instead of those traps he advocated the adoption of valve-syphon traps. Every one of the instances of the defects in the joints which he illustrated was connected with a case of disease or death.

## Surgeon-Major Charles Cuffe.

THIS gentleman, who was one of the officers who recently received at the hands of her Majesty the Insignia of the Order of the Bath, for service rendered in the Zulu war, entered the Medical Department of the Army in 1863, serving in India and Arabia. He was appointed Assistant-Surgeon to the 11th Hussars, and, after several years service in his regiment, was promoted to the rank of Surgeon-Major. In October, 1877, he proceeded to the Cape of Good Hope, arriving just at the commencement of hostilities against the Galekas. He served as principal medical officer of the Transkeian field force under Colonel Glynn, C.B., throughout the campaign, and at the conclusion received the thanks of the Director-General of the Army Medical Department. He then proceeded to the Transvaal, and joined the forces there being organised under Brigadier-General Wood, V.C. He acted as principal medical officer throughout the Zulu campaign, and was favourably mentioned in despatches. He again received the thanks of the Director-General. Surgeon-Major Cuffe is the son of the late Daniel B. Cuffe, of Dublin, received his professional education at the Catholic University Medical School and the Richmond Hospital. As a student he won several prizes in literature, science and medicine. His brother, Surgeon George M. Cuffe, also serves her Majesty in the Naval Medical Service.

## Mr. R. M. Bellew, Irish Local Government Commissioner.

WE understand that Mr. Bellew, who is the second Commissioner of the Irish Local Government Board, is in very delicate health. We notice the circumstance because it is our duty to urge—which we do with our utmost emphasis—that, in case Mr. Bellew finds it necessary to retire from office, either his office should be abolished, or its functions—if there be any—should be actively fulfilled. Mr. Bellew draws, and for many years has drawn, £1,200 a-year for salary, and during the whole period we have never even been conscious of his existence as an Irish Local Government administrator. Mr. Henry Robinson we know, and Dr. Croker King we know, but who is he? Now, we don't for a moment doubt that the services of a third commissioner are necessary to the working of so comprehensive a department as the Irish Local Government Board, but we are apprehensive that, as the general elections approach, and it becomes necessary to provide for a multitude of Government hangers-on, another job may be done at the expense of the Irish poor and another analogue of Mr. Bellew pensioned off as a sinecure commissioner.

The weak point of the Irish Local Government Board has always been that it is an *imperium in imperio*—an establishment in which there has been one dictator and no other person plucky enough to possess an opinion at variance with that of the prevailing autocracy. *Si monumentum queris, circumspice.* If we desire to know the effect of such a system we have only to look to the state of the Irish sanitary service, and we shall find there the mark of Sir Alfred Power's powerful hand and of his prejudices against reform, and the utter weakness of those who were supposed to divide with him the administration of the department. If we are likely to be favoured with a successor to Mr. Bellew of his own exceedingly neutral colour we should say that Mr. Herbert Murray and the cheese-paring Departmental Committee may effect a good stroke of business by drawing its pen through the office and leaving the £1,200 a-year in the Treasury coffers.

## The Dublin Sanitary Commission.

WE observe that the *Dublin Freeman's Journal* and the *Evening Telegraph*, both of which are the mouth-pieces of Mr. Gray, M.P., now Lord Mayor, and heretofore the Chairman of the Public Health Committee of the Dublin Corporation, have taken in hand the task of improving, in the interest of the Corporation, the report and evidence of the Dublin Sanitary Commission. They seek to effect this purpose by maintaining that the Commission was only charged to investigate the Liffey and the main drainage, and, therefore, ought not to have touched the general question of the causes of the appalling mortality in Dublin, and, *ergo*, ought to cut out from the report the facts as to the prevailing filth of the city, the awful house accommodation of its poor, and, in fact, all the evidence bearing upon this part of the subject. We need not have troubled ourselves with these pronouncements of our contemporaries, for we quite anticipated that champions of the Corporation would make strenuous efforts to save it from the Parliamentary exposure of its indefensible neglect of its sanitary duty, and from the opening of the horrible state of the city to the public gaze; but we think the articles to which we refer worthy of notice, because we are apprehensive that the Commissioners might allow their action to be influenced by the wishes of the Custom House, the Castle, or the City Hall—might therefore think it inexpedient to let the House of Commons know the naked truth as sworn to before the Commission, and might, therefore, be disposed to emasculate the report and evidence. We should be extremely sorry if the report, when issued, should bear any evidence of this policy, for the Commission has won the confidence of the citizens by the independent line which it took, and it would forfeit that confidence as completely if it condescended to trim its report for the behoof of the Dublin Corporation, the chief secretary, or the Local Government Board. The Commission, after all that has been said and written, must know full well that if the Liffey were as pellucid as they could wish, and soap as plentiful as Dublin mud—these would not suffice to wash the Corporation clean of its negligence and obstructiveness in sanitary matters, and, therefore, an attempt to do so by the emasculation of the report, would be as futile as it would be objectionable. It is far better that "the truth, the whole truth, and nothing but the truth" should come out, and we can then afford to let the *Freeman's Journal* and the *Evening Telegraph* explain away the facts if they can.

## Traffic in English Pseudo-Charity Votes.

A STRIKING commentary upon the abuses of English pseudo-charity administration is supplied by the *Exchange and Mart*, a paper devoted to the barter of articles between its readers—of whom it possesses a multitude. The latest development of its system is the establishment of a separate section in its pages to the sale and "swapping" of votes for hospitals and other institutions which call themselves charitable.

Through the agency of this journal any person who thinks he has—by a subscription or in some other way—established a right to "squat" anyone he pleases upon the resources of the institution will be enabled to impose upon the "charity" some person whom he never heard of, and at the same time to make a little personal profit by acquiring, in return, the opportunity of "squatting" one of his own friends or relatives on some other institution for which that friend or relative has, probably, neither need nor fitness.

The editor of the *Exchange* does not make any pretence of doubting the existence of gross abuses of the charity voting system, but he simply observes that, as they do exist, his journal may as well make a little profit by starting a trade in them.

"It is principally," he says, "because we admit the evil of the sale of votes, as at present managed, that we propose to establish a department for their ready disposal, for we think it will be admitted that an open market would tend to bring down prices to their proper level. That there are many inmates of the various homes who are not fit objects of charity is doubtless true, but the onus rests with the committees which sanctioned the nomination. No doubt many persons have feelings of great responsibility in the giving of their votes, but that this is so in the majority of cases we should question, and we must deal with things as they are rather than as we should wish them to be."

When the benefits derivable from the contributions of the benevolent have become the subjects of simple buying and selling, we are certainly entitled to ask whether institutions which permit such a means of distributing their bounty are charities at all, or are not rather guilty of obtaining the money of soft-hearted but foolish people upon the false pretence that they will apply it for the advantage of the deserving poor. From such inquiry arises the further question whether—taking the average of "charitable" institutions in London—even one half-crown out of each pound of subscribed money ever reaches a deserving poor person? and, finally, whether the whole charity organisation, as it stands, is not a system in which the evil greatly outsteps the good, and which enables persons—who are not benevolent, but only ostentatious and selfish—to obtain credit for being kind-hearted and self-sacrificing when, in truth, they are only qualifying themselves to be the patrons of certain mean, lazy, and unscrupulous people who desire that the public should save them the trouble of supporting themselves during sickness or infirmity.

## Ill-health of Dublin.

THE deaths registered in the Dublin district during the week ending 27th December, represent an annual mortality of 44·8 in every 1,000 of the population.

The death-rate in eight large towns, districts of Ireland (including Dublin), last week was 38·9. In Cork the rate was 47.

In 20 large English towns, inclusive of London (in which the rate was 27·1), the death-rate averaged 27·4, in Glasgow, 27·3, and in Edinburgh, 20·9.

Fifty-eight deaths from zymotics were registered, 26 over the average for the fifty-second week of last ten years.

The registered deaths from small-pox (5) are one in excess of the number for the preceding week, but only 17 new cases of the disease were admitted into the Dublin hospitals, against 19 in that week.

Upon comparison with English, European, and Asiatic cities it appears that Dublin outstrips the world in its unhealthiness—calculating upon this week, which is by no means exceptionally bad. Excepting Plymouth, the worst record of the week in England is that of Liverpool, 36·0, while that of Dublin is 44·8. Calcutta shows for 370 and Alexandria ; 40·0 but no other city—no matter where situated—approaches Dublin in unhealthiness.

## Sea-water at Home.

THE undoubted efficacy of sea bathing as a health restorative is so widely admitted, that it is reasonable to anticipate no opposition will be made to a bill having for its object the attainment of this great sanitary desideratum. A private bill for this purpose will, next session, be presented to Parliament, its promoters being prepared with a scheme for providing to the metropolis a constant supply of sea-water from the English Channel. A feature of the proposal is that almost every middle-class family will be enabled to participate in the advantages to be derived from its adoption, a yearly rental of thirty shillings per £50 of house-rent being the suggested price for the luxury. The scheme carries its own recommendation, and the boon it will confer would be cheap at a much more considerable price than that suggested.

## The late Professor Boll.

AN eminent physiologist has recently paid the debt of nature in the person of Francis Boll, Professor in the University of Rome, who died December 19th. By birth a German, the deceased *savant* had made Italy his home, and in the place of his adoption had prosecuted a number of researches and special investigations, by which his fame has been made known in every scientific circle. To him is due much of the credit owing to those who have insisted on the importance of physiology as a basis of medicine, and universal regret will be felt at his death at the early age of 30. He was born at Brondenburg in 1849, and graduated in medicine and surgery at Berlin in 1869. Here he assisted Dubois-Reymond in his physiological laboratory for some time, but was compelled, through ill-health, to seek the warmer climate of Italy, when in 1873 he received an appointment in the University which he graced as professor for two years, having been elected to the chair he held at his death in 1877. His most important work bears on the arterial circulation of the retina.

## Wyatt Edgell Prize.

The Sanitary Institute of Great Britain announces that, through the munificence of the Rev. E. Wyatt Edgell, late Honorary Treasurer to the Institute, a post he has been compelled to resign through ill-health, it is enabled to offer a prize of £200 for the best essay on

"The Cause of Hereditary Tendencies in Health and Disease." The composition must be sent in by August 1st, 1880, and will be adjudicated on by Drs. B. W. Richardson, F.R.S., and W. Farr, F.R.S.

### Guy's Hospital.

HAVING accepted the responsiblity of being the first to draw general attention to the unfortunate state of affairs at Guy's Hospital, we feel called upon to repeat our emphatic disapproval of the ill-judged and persistent opposition on the part of the treasurer to the wishes of the whole staff of the hospital. The disastrous effects that have followed the short-sighted policy of this official are already productive of much evil if we can judge from the frequent expressions of uneasiness given vent to by those on the spot. And especially is it to be regretted that the protest raised against the new arrangements on the part of the physicians, surgeons, and assistants of the hospital has been treated with nothing more than a curt and cavalier reply to the effect that no interference with these changes will be tolerated. Since the repeated suggestions of those most fit to offer them are set at nought, by treasurer and his nominee, and there is every prospect that the best interests of a great and important public charity are thereby imperilled, there remains no course open to those who are pained by the effects that are being made daily evident, damaging as they are to the efficiency of the institution, but to enlist the sympathy and aid of the outside public. It must not be forgotten that Guy's Hospital exists for the public good, and that the public will, when called upon, respond to the demand for a removal of abuses that are endangering the advantages it has inherited. But, so long as it is possible to hope that a private settlement of the matter in dispute can be arrived at, it is greatly to be desired that no appeal to the general public should be made. We trust that the treasurer will quickly discern the truth of this, and being guided by the universal disapprobation of the course he has pursued, assist in rescinding the arbitrary regulations that have proved so destructive to the hospital over which he has control.

### Paying Hospital Patients.

THE discussion which took place some time ago relative to the advisability of admitting paying patients into St. Thomas's Hospital, and which then resulted in an opinion unfavourable to the scheme, it is probably about to be revived. It is understood that the authorities of St. Thomas's have submitted a draft proposal to the Charity Commissioners to provide accommodation for such patients. The scheme provides that a separate pavilion shall be set apart for the purpose, in charge of which a medical officer will be appointed, but the occupants will be admitted the option of being attended by particular practitioners of their own choosing, in which case, of course they will pay the extra expense of such attendance. Provision is also made for the admission of patients into the general wards, who shall be subject to the payment of reduced fees, amounting only to the cost of their maintenance. The reasons for and against the proposition are numerous, and in the absence of any sufficient data on which to base conclusions, it is scarcely possible to discriminate with any accuracy between the two sides of the question. On the one hand, there is undoubtedly a very large class of persons who would be benefited by such a system of medical relief—who are often incompetently treated because of the many difficulties in the way of adequate attention to the minutiæ of nursing, &c., in any but a properly-appointed place with properly-appointed and trained assistants to carry out the detailed orders of the professional attendant. On the other there is the grave objection that the proposed plan must deprive the general profession of a large number of fee-paying patients, who, but for the refuge that would be afforded them in a hospital, have no resource but to be ill at home, and receiving the regular visits of the family doctor. It cannot be concealed, however, that the tendency is toward some such plan as that proposed; and it will probably be wiser to admit the necessity at once, than to delay action under pretence of discussing possibilities. We shall return to the subject again ere long.

### Presentation at the Meath Hospital and Co. Dublin Infirmary.

A VERY pleasing ceremony took place on New Year's morning at the above-named hospital—the entire medical staff being present—the occasion being the presentation of a gold keyless watch to Mr. William E. Crozier, L.R.C.S.I., House Surgeon and Resident Medical Officer, by the Medical Board. Mr. Porter (senior surgeon) addressed Mr. Crozier on behalf of his colleagues, and expressed in feeling terms the pleasure which it gave him to present this New Year's gift, assuring Mr. Crozier that his efficient services as house surgeon had given the greatest satisfaction to the medical and surgical staff. Mr. Crozier replied in suitable terms. The watch bore on its case the following inscription:—"Presented to William E. Crozier, Esq., L.R.C.S.I., by the Medical Board of the Meath Hospital, as a slight token of their esteem and regard January 1st, 1880."

### Dr. Evory Kennedy.

WE are pleased to learn that his Grace the Lord Lieutenant of Ireland has, on the recommendation of Viscount Monck, Lieutenant of the county and city of Dublin, appointed Evory Kennedy, J.P., M.D., of Belgard, Clondalkin, to be Deputy Lieutenant for the county, in place of William Caldbeck, Esq., deceased. Dr. Kennedy is a very well-known and highly-esteemed citizen of Dublin, a former President of the King's and Queen's College of Physicians and of the Irish Medical Association, and an ex-Master of the Rotundo Hospital, and a distinguished obstetrician of his day. He is, so far as we know, the only member of our profession holding the Deputy Lieutenancy in Ireland.

### The Death Roll of the Profession in Ireland, 1879.

THE following names appear in the Obituary List of the "Irish Medical Directory" for the new year:—W. O'B. Adams, H. Atkinson, R. Atkinson, A. Banks, James Barker, John Barker, G. P. Barry, H. Blyth, J. Brock, S. W. Brown, W. Burden, J. Burke, W. M. Burke, O.

H. Chambers, P. Clarke, S. Coates, J. Coppinger, R. Cross, J. Daly, J. N. Davis, J. Elliott, D. Fitzgerald, J. Flanagan, J. J. Furlong, J. Gentleman, M. Gilligar, J. Grealy, R. Hays, W. Hegarty, E. Hogan, A. Ireland, A. Irvine, B. Jagoe, J. Johnston, B. Kavanagh, J. Kiernan, J. Kelso, A. Laughlin, E. Lawless, E. Ledwich, B. F. McDowell, W. McKee, R. McNane, W. Magill, R. Macgrath, H. Maunsell, H. Molloy, D. Mooney, W. Moore, J. Morewood, B. Morrow, J. Murphy, W. Murphy, H. Nixon, D. O'Connell, E. O'Kelly, M. O'Meara, J. Powell, J. P. Quinlan, J. Shaw, C. Smith, R. Smyth, E. Soden, H. H. Stewart, W. Thompson, R. Tarney, W. Wade, R. Wallace, J. Wallace, C. Walsh, P. Walsh, J. White, R. P. White, J. Whitla, R. F. Wilson, F. Woodhouse, and A. A. Woods.

### Surgeon-Major Isidore Bourke.

RESPECTING this gentleman, to whose heroism at the Bala Hissar we recently referred, we find the following letter published in the *Freeman's Journal* :—

"SIR,—In the paragraph in the *Freeman's Journal* of last Saturday respecting the conduct to General Roberts, it is stated that Dr. Bourke was expelled the camp for having given publicity to the fact that atrocities were committed. I have only now seen the paragraph, which needs correction. I may mention that Surgeon-Major Isidore Bourke is my brother. Previous to the 12th of last month arrangements were made for the return to India, from General Roberts' camp, of sick and wounded men, and Dr. Bourke was selected to take charge of them. He subsequently left on that duty, and on the 25th he was *en route* for Peshawur in charge of the sick and wounded. He had been in command of the Ambulance Corps, in discharge of which duty he received high praise from General Roberts, who also commended him highly for his heroism on the occasion of the explosion at the Bala Hissar. The success of Dr. Bourke in Cabul has been recently noticed in several leading journals. There was no ground for stating that Dr. Bourke was expelled the camp, and I trust that the statement will be corrected at once. I have just received the *Medical Press* of the 17th December, in which Dr. Bourke's conspicuous bravery is noticed.—Yours faithfully, WALTER M. BOURKE."

PRINCE LEOPOLD, Vice-Patron of University College Hospital, has consented to preside at the annual festival, which will take place early in March next.

A PAIR of female twins, united from the breast bone to the lower part of the abdomen, is reported from Bombay. They are eight months old and in good health.

THE Right Hon. W. H. Smith, M.P., First Lord of the Admiralty, has consented to preside at the fifty-ninth annual Court of the Governors of the Dreadnought Seamen's Hospital, at Willis's Rooms, in February next.

THE *Philadelphia Reporter* says that a leading wholesale drug house in St. Louis sold, in 1878, for two months in the fall, quinine at the rate of a thousand ounces a day. This year their sales at the same time did not average over one hundred ounces a day.

THEIR Royal Highnesses the Prince of Wales and the Duke of Edinburgh have consented to become patrons to the French Hospital in London. The committee have voted the erection of a marble tablet to commemorate the visit of their Royal Highnesses to the Hospital in July last.

THIS month it is intended to celebrate the fiftieth anniversary of the formation of temperance societies in England, at Bradford, that being the town in which the first society is stated to have being formed in 1830. The celebration will take the form of a national demonstration, and conferences will be held on the various aspects of the temperance question.

DR. BUMSTEAD, of New York, author of the well-known work, "On Venereal Diseases," has just died. Deceased possessed a lucrative practice in New York, and his funeral was attended by a large body of the profession of that city. Dr. Bumstead was well and favourably known in this country, and had but recently finished the revision of an enlarged edition of his work.

IN consequence of the extensive and virulent outbreak of measles in Hull, the School Board, and many of the managers of large public schools have determined to extend the Christmas holidays of the scholars, in order to prevent, if possible, the further spread of the disease. Out of the 600 houses visited by one inspector, there were 100 in which the epidemic either was or had been prevalent.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Brighton 17, Sunderland 17, Sheffield 19, Portsmouth 21, Edinburgh 21, Oldham 24, Birmingham 25, Bradford 26, Norwich 26, Wolverhampton 26, London 27, Leeds 27, Hull 27, Glasgow 27, Newcastle-upon-Tyne 28, Manchester 29, Bristol 30, Salford 31, Leicester 31, Nottingham 33, Liverpool 36, Dublin 45, and the highest rate 46 in Plymouth.

LAST week the death rate from the seven principal zymotic diseases ranged from 0·0 and 0·5 in Wolverhampton and Oldham, to 6·9 in Liverpool, 7·3 in Dublin, and 9·1 in Plymouth. Scarlet fever showed the largest proportional fatality in Newcastle-upon-Tyne, Nottingham, and Bristol; and measles in Plymouth, Hull, Liverpool, Nottingham, and Leeds. Diphtheria caused 11 deaths in London, and 4 in Birmingham. There were 652 deaths last week in London from diseases of the respiratory organs. Two more fatal cases of small-pox were recorded in London, 5 in Dublin, but not one in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ENTERTAINMENT AT THE GLASGOW ROYAL INFIRMARY.—An interesting gathering took place at the Glasgow Royal Infirmary on the 26th ult. Hitherto the Lord Provost has been in the habit of treating the nurses of this institution to an excursion into the country, but this year instead a chamber concert was agreed upon. The members of the Free Anderston Church Choir gave their services on the occasion. The Lord Provost (Collins) presided, and among the ladies and gentleman present were Mrs. Collins, Lord Dean of Guild Mirlees, Mr. James King of Levernholm, Mr. William Stirling, Mr. William McEwen, &c. An excellent concert was enjoyed. Mr. McEwen and others made short speeches, and after the "speechifying" an adjournment was made to the supper-room, and after supper there was a dance.

**Glasgow Royal Infirmary.—Professor Gardiner on the Duties of Nurses.**—The usual New Year's Day meeting with the nurses belonging to the Royal Infirmary was held in the lecture room on the 1st inst. There was a large attendance of the nurses, and a number of ladies and gentlemen who take an interest in the institution were present. The tables in front of the seats were laden with toys, which had been kindly sent for the youthful patients by friends, while the walls were nicely decorated with devices and evergreens. The Lord Provost occupied the chair, and amongst those present were Sir James Watson, Sir James Bain, Bailie Farquhar, Mr. Wm. McEwen, Mr. Peter Clinston, Mr. James King, Mr. Hanan, Professor Gardiner, Dr. Wilson, &c. After an address from the Chairman, Dr. Gardiner afterwards delivered an address, touching on the principal points which should be observed by nurses in the discharge of their important duties. Years ago the remark that their's was a great and noble profession would have been met with sneers. But it was very different now, and it was one of the features of that revolution which had love and science at the bottom of it. This we owed in a large extent to Miss Florence Nightingale. Their profession of nurse had a high aim, and it was expected that those who entered it did so for the love of it. He offered many valuable suggestions to nurses, and concluded by referring to the many improvements that had taken place in the system of nursing in recent years. Afterwards many of the wards were visited by the ladies and gentlemen.

**Death-Rate of Glasgow.**—The deaths in Glasgow for the week ending with Saturday, the 27th ult., were at the rate of 27 per 1,000 per annum, against 31 in the preceding week, and 36, 23, and 27 in the corresponding weeks of 1878, 1877, and 1876.

**The Representation of Edinburgh and St. Andrew's Universities.**—Zealous efforts, it is said, are being made to induce Sir William Gull to come forward as a candidate for the Universities of Edinburgh and St. Andrew's in opposition to Dr. Lyon Playfair. The Liberals consider the return of the latter in any case most certain.

**Deaths from Excessive Drinking.**—Five deaths occurred in Scotland at New Year time from excessive drinking. Three took place in Edinburgh and two in Dundee.

**Registrar-General's Report.**—The return of births, deaths, and marriages for the week ending December 27th says :—The death-rate in the eight principal towns during the week ending December 27th, 1879, was 25·1 per thousand of the estimated population. This rate is 6·8 under that of the corresponding week of last year, and 3·4 under that of the previous week of the present year. The lowest mortality was recorded in Perth, viz., 17·6, and the highest in Paisley, viz., 35·1. The mortality from the seven most familiar zymotic diseases was at the rate of 3·3 per thousand, being slightly under the rate recorded for last week. Whooping-cough continues the most prevalent epidemic. Acute diseases of the chest caused 209 deaths, being 38 under the number recorded during last week.

**Elgin.—Death of Dr. Taylor, Easton.**—The death is recorded of Dr. James Taylor of Easton, Elgin. The deceased obtained an appointment as physician in Bengal, in the East India Company's Service when at the age of twenty-two, and for twenty years he acted as medical superintendent of the Calcutta Infirmary. Thirty-three years ago he returned to his native town, Elgin, and chiefly devoted his leisure time to studies of archæology and geology.

# Obituary.

## MR. HANCOCK, F.R.C.S.

It is with a profound feeling of regret that we are so soon again called upon to add to the obituary of eminent members of our profession given in our summary of last week the name of Henry Hancock, F.R.C.S., who was for so many years connected with the Charing Cross Hospital. He expired from an acute attack of icterus, the gravity of which he seems to have very much underrated, on New Year's day at his country house, Standen Chute, near Andover, whither, after an active and laborious life, he had retired only three or four years ago to spend the remainder of his days. In 1834, on the completion of his studies at Westminster Hospital, where he had the advantage of seeing some of the best surgery of the day, Lynn, Carlisle, Guthrie, &c., being then in the zenith of their fame, Mr. Hancock was admitted a member of the College of Surgeons. Very soon after he became connected with the School of Medicine of the hospital, and was appointed demonstrator of anatomy. Books for the use of the student were not so numerous as they are now, and he sought to add to the few in use by translating Velpeau's "Anatomy," but it never attained to a large sale or to a distinguished place amongst our class books. In 1843 he was elected a Fellow of the College. Not long after an opening occurred at the Charing Cross Hospital by the compulsory retirement of the late Mr. Pettigrew, and after a smart contest, the late Mr. Partridge being his opponent, he was elected Assistant-Surgeon to the hospital. The early death of Mr. Howship led to his obtaining the full surgeoncy at an unusually early period of his professional life. At this time the hospital had but few students, and had some difficulty to hold its own against the older and well-endowed hospitals. Mr. Hancock, however, worked away with a will, and his reputation as a bold and dexterous operator soon became recognised, and did much towards raising the reputation of the hospital and school. He was known as one of the first surgeons who attempted the removal of the jaw for the arrest of malignant disease. He was also the first to remove the os calcis, and adopt a new method of operating for strangulated hernia. In 1850 the College of Surgeons, being then under the domination of the surgeons of the larger hospitals, made an attempt to break up the smaller schools of medicine. The Charing Cross Hospital came under its ban, but Mr. Hancock, assisted by his fellow-workers and old pupils, successfully resisted this act of gross injustice, and from that time to the present the school has been gaining in importance. In 1848 Mr. Hancock was unanimously elected President of the Medical Society of London. In 1851 he became "Lettsomian Lecturer," and delivered an important course of lectures on "The Anatomy and Physiology of the Male Urethra, and on the Pathology of Stricture of that canal." He subsequently filled the office of treasurer and trustee, in which capacities he rendered valuable services to the society, and was for many years a constant contributor to its Transactions and discussions. In 1852 he became Surgeon to the Royal Westminster Ophthalmic Hospital, and for several years delivered a course of lectures on eye diseases at this institution ; and here his name became associated with an operation for the cure of glaucoma known as division of the ciliary muscle. He was also surgeon of the Royal Infirmary for Children, Waterloo Road ; consulting surgeon of the Maidstone Eye Hospital. As Fellow of the Royal Medical and Chirurgical Society he contributed to its Transactions a course of lectures on "Dislocation and Injuries of the Shoulder-joint." In 1863 he was elected a, Member of the Council of the Royal College of Surgeons and from that time to the day of his death he took the greatest interest in its affairs. In 1865 he became Professor of Human Anatomy and Surgery to the College, and as "Arris and Gale" Professor he delivered a course of lectures on a subject he had long made a special study of, "The Anatomy and Surgery of the Human Foot and Ankle-joint." These lectures, subsequently published in a separate form, may be regarded as a standard work, and as affording the best and most practical information on this important surgical subject.

In 1870 Mr. Hancock was elected a Member of the Court of Examiners, the arduous duties of which he fulfilled with tact and judgment. In 1872 he was chosen to fill the highest honour his colleagues could confer upon him, that of President of the College, and the next year he was appointed to deliver the Hunterian oration. On his retirement from the Senior Surgeoncy of Charing Cross Hospital, he was at once elected Consulting Surgeon, his colleagues and old pupils subscribing for a testimonial, which, by desire of Mrs. Hancock, took the form of a portrait painted by Richmond. Mr. Hancock was a decidedly popular teacher, an excellent and successful operator, a staunch friend, and a bright ornament to the profession which he studied to adorn and improve, and leave in better and more advanced state than he found it. His loss will be deeply felt by a large circle of sympathising friends and acquaintances. He leaves a widow, a son, now exercising his judicial duties in Antigua, and a daughter, married to Captain Heaton.

◆

## DR. HERMANN FREUND.

It may be mentionedi n connection with the death of this gentleman, which occurred last week, that until he started the idea in 1844, there was no hospital in London devoted to foreigners where they could be attended by medical men of their own nationality. With such a mixed and ever-changing population the want became so apparent that Dr. Freund some thirty-five years ago set to work to found an hospital for Germans, and mainly through his original suggestions, energy of purpose and devotion to the cause he had undertaken, this nationality has now in London a large and flourishing hospital, with a regular staff, and beds for 125 in-patients, which will compare in efficiency and good management very favourably with most of the larger institutions. Dr. Freund, though possessing Austrian degrees, held the position of Inspector-General of Hospitals in the British Forces during the Crimean campaign. Amongst the poor Germans in London he was a great favourite, from the interest he always took in their welfare, and the kindly disposition always evinced towards them; and his loss will be greatly felt by them. Dr. Freund had for a long past suffered from severe bronchial attacks, and the excessive cold and fogs of the present winter developed the complaint to which he succumbed last week at his residence in Finsbury Circus.

◆

## NOTICES TO CORRESPONDENTS.

Dr. Braithwaite.—Illustration received thanks.

Dr. Grelatz.—With pleasure.

Mr. Ensor.—Consult a respectable practitioner in your own town; we do not prescribe.

Dr. Carson, Cincinnati.—Many thanks.

Dr. L. B. B.—The subject is one from which much good might arise by discussion

### COCKING'S PATENT POROPLASTIC SPINAL JACKETS.

*To the Editor of the* Medical Press and Circular.

Sir,—The interest you have shown in my invention induces me to ask your insertion of the following:—

A glance at your advertising columns will show your readers that my invention is being pirated, and thus a valuable and important addition to spinal appliances may get into undeserved disrepute. It would be well, therefore, if, before ordering jackets, surgeons would apply to me for a list of agents accredited to supply them, and at the same time I shall gladly give any information required as to the method of application, and if convenient to London or Plymouth, be pleased to assist any surgeon in his first application—I say first, for after seeing one fitted he will not (unless the case be a very severe one) require further aid.

Yours respectfully,

7 Mandeville Place, Manchester Square, London, W.

J. T. Cocking.

The Medical Society of the King and Queen's College of Physicians of Dublin will meet on Wednesday next, at 8 o'clock, at the College, when the following communications will be made:—Dr. Hayden, "Notes on a Case of Wandering Kiddey, with remarks."—Prof. W. Moore, to narrate some Anomalies in Fever.

Epidemiological Society of London.—This (Wednesday) evening, at 8 o'clock, Dr. Norman Chevers, "Notes on the Relapsing Fever of India."—Surgeon-General Ross, "Remarks on Epidemic Diseases (Men and Animals) in the Colony of Natal."

Analyst.—The disinfectant is manufactured by Mr. White, Chemist, Kennington Road, S.E.

Royal Institution.—On Tuesday, Jan. 13, at 3 p.m., Prof. Schäfer, "On the Physiology of Muscle."

A Student.—Yes, a book upon which you may place implicit reliance.

Dr. Connolly Norman.—In our next; thanks.

Clinical Society of London.—Friday, Jan. 9, at 8½ p.m., Annual Meeting; Election of Officers.—Report of the Committee appointed to inquire into the Deleterious Effects which follow the prolonged and continuous use of Chloral in ordinary doses.—Dr. Goodhart, "On a Case of Rheumatic Fever treated with Salicylate of Soda, and terminating fatally."—Mr. Pick, "On a Case of Subastragaloid Dislocation."—Dr. Hewan (for Mr. Adam), "On a Case of Bullet-wound of the Lung."—Mr. Brodhurst will show a Case of Genu Valgum (shown also last session).—Mr. T. Smith will show (1) a Case of Spontaneous Gangrene; (2) two Cases of Cystic Hygroma; (3) a large Nævus.

Royal Institution.—On Friday, Jan. 16, at 9 p.m., Prof. Dewar, "Investigations at High Temperatures."

Dr. Pantaleoni and Dr. Hoggan.—Letters unavoidably held over in consequence of Index appearing in present number.

◆

### VACANCIES.

Ballinasloe Union, Lawrencetown Dispensary.—Medical Officer. Salary, £112, with fees, and £15 as Medical Officer of Health. Election, Jan. 13.

Bedford General Infirmary.—Resident Surgeon. Salary, £100, with board. Immediate application to the Secretary.

Bristol Royal Infirmary,—House Physician. Salary, £100, with board. Applications to the Secretary on or before Feb. 2.

Dunfanaghy Union, Falcaragh Dispensary.—Medical Officer. Salary, £100, with fees, and £10 as Sanitary Officer. Election, Jan. 16.

Kent County Asylum.—A Senior and a Junior Assistant Medical Officer Salaries, £120 and £150 per annum respectively. Applications to the Medical Superintendent, Burning Heath, near Maidstone, before Jan. 20.

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150, with board. Applications to the Chairman of the Board by Jan. 17.

North Dublin Union Workhouse.—Medical Officer. Salary, £150. Election, Jan. 27.

Roscrea Union, No. 1 Dispensary.—Medical Officer. Salary, £100, with fees, and £10 as Medical Officer of Health. Election, Feb. 2.

◆

### APPOINTMENTS.

Cranny, J. J., A.B., M.D., F.R.C.S.I., Surgeon to Jervis Street Hospital, Dublin.

Cunynghame, R. J. B., M.D., a Physician to the Hospital for Sick Children, Edinburgh.

Cutler, P. A., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer to the Fanning Institution, Waterford.

Freer, E. L., M.R.C.S.E., Honorary Assistant Surgeon to the Birmingham Orthopædic and Spinal Hospital.

Gage, R. C., M.B., M.Ch. Univ. Dub., Medical Officer to the Scotstown Dispensary, Monaghan Union.

Gill, J., M.D., Surgeon to the Stratford-on-Avon Infirmary.

Langton, J., F.R.C.S.E., Consulting Surgeon to the City of London Lying-in Hospital.

Leigh, T., L.R.C.P.L., M.R.C.S. & L.M., Medical Officer for the Central District of the Parish of Brighton.

Letts, E. A., Ph.D., Professor of Chemistry at the Queen's College, Belfast.

◆

## Births.

Frazer.—On Dec. 30, at Armagh, the wife of Henry Fraser, L.R.C.S.I. of a daughter.

◆

## Deaths.

Boulland.—On Dec. 22, at 36 Woodhouse Street, Leeds, Alfred B. Boulland, L.R.C.P.L., M.R.C.S.E., &c., aged 42.

Day.—On Oct. 23, at Auckland, New Zealand, Richard Day, M.D., formerly of Cork, aged 74.

Freund.—On Dec. 29, at 7 West Street, Finsbury Circus, Jonas Chas. Herrmann Freund, M.D., aged 71.

Jackson.—On Dec. 26, at Harley Street, London, W., Ernest Carr Jackson, M.R.C.S.E., aged 26.

Jackson.—On Dec. 21, at Darlington, T. Hayes Jackson, F.R.C.P.Ed., aged 69.

Long.—On Dec. 29, at Hardman Street, Liverpool, Jas. Long, F.R.C.S., aged 70.

Moss.—On Dec. 6, on board the steamer *Senegal*, James West Moss, L.R.C.P.Ed., aged 34.

Nicol.—On Dec. 20, at Church Road, Higher Tranmere, Wm. Nicol, M.B., of Ayr, aged 22,

Powell.—On Dec. 27, at Roscrea, co. Tipperary, John Allman Powell, M.R.C.S.E.

Sadler.—On Dec. 28, at Winterton, near Brigg, Joseph B. Sadler, M.R.C.S.E., L.S.A.L., aged 70.

Sweeting.—On Dec. 22, at Reading, Robert Bray Sweeting, M.R.C.S., late of Basingstoke, aged about 47.

Tassell.—On Dec. 20, at Dover, Robert Tassell, M.D., formerly of Canterbury, aged 54.

Walker.—On Dec. 26, William Charles Walker, M.R.C.S.E., of Shepton Mallet, aged 66.

Woollett.—On Dec. 18, at Monmouth, John Moore Woollett, M.R.C.S., aged 65

### ON HOUSES IN WHICH ZYMOTIC DISEASE RECURS. (a)

By CHARLES A. CAMERON, M.D.,

Fellow and Professor of Hygiene and Chemistry, R.C.S.I., S. Sc. C. Camb.; Superintendant Medical Officer of Health, Dublin; President of the Society of Medical Officers of Health.

In Dublin it has been found that various contagious diseases reappear several times in the same house. In some courts as well as houses, it has been noticed that small-pox, scarlatina, and other zymotic diseases periodically make their appearance. The narrow lane running from South Great Brunswick St. to Townsend St. is an example of this unhealthy kind of court. It consists of a poor class of houses, with but little space in the rear of some of them, and no open space behind the others—overshadowed by ranges of loftier houses, causing deficiency of light and stagnation of air. In this court Asiatic cholera made an early appearance during its last visitation, and here one of *the* first—if not the first—cases of small-pox occurred in the epidemic of 1871. I have found that the houses in Tennis Court have had all kinds of zymotic diseases in them, and the whole place seems to be saturated with contagia. It is evident that disinfection, as generally performed in tenemental houses, and the occasional application of whitewash to them, as enforced by the sanitary authorities, are often inoperative in rendering such houses as those in Tennis Court healthy dwellings. The only remedy for such an unsanitary state of things as that which prevails in purlieus like Tennis Court is to raze the houses. This is the course which I have recommended to be done in this particular instance, and which recommendation I have reason to believe will beacted upon next year.

When a house appears to be seriously affected by the contagium of one or more of the zymotics, it certainly should be cleared out and subjected to a close sanitary inspection. It will probably be found that the house-drains are defective—that the water-closet is out of order—that there is an ill-kept *petit* and an offensive ash-pit, or some other sanitary defect—perhaps a great many defects—present. Such a house subjected to a thorough disinfection, and having all its interior wall surface hot lime-washed, will, when put into proper repair, be probably as healthy a house as any other of the same class. The duty of the sanitary authority is clear in the case of notoriously unhealthy houses, the sanitary conditions of which are obviously bad. Occasionally, however, contagious disease reappears in a house which is well provided with sanitary accommodation and in good repair—perhaps not long built. What is to be done in such a case? The landlord asserts that the house is in perfect order, and examination of the premises fails to disprove this assertion. I have met with some cases of this kind which have rather embarrassed me. A house in Francis Street, superior to most houses in that locality, and not long built, had several cases of small-pox in it one after the other. After each case the room in which the patient had been located was disinfected and lime-washed, but these processes did not apparently prevent a recurrence of the disease. Now, in the case of this house, would it not be justifiable to have it compulsorily cleared of its inmates and their belongings, and the whole house subjected to thorough disinfecting and general cleansing? Would it, in fact, not be desirable to close up for a time every house in which—during say one year—three or four successive cases of infectious disease occurred? The objection to this is, that the people and the furniture and clothing of an infected house are dispersed, and may distribute infection through half a dozen other localities. It is most important that a record be kept of the cases of contagious disease in every house within the jurisdic-tion of the sanitary authority.

---

(d) Read at a meeting of the Society of Medical Officers of Health, held at the Royal College of Surgeons, Dublin, December 10th, 1879.

It would be very desirable if there were a refuge established for persons obliged to leave their dwellings for a short time until the latter were purified. It is difficult, if not impossible, to thoroughly disinfect rooms unless the tenants are kept out of them for a few days. When a case of infectious disease occurs in a tenemental dwelling, and the patient has been restored to health, removed to hospital, or buried, how is the room which he has inhabited to be purified properly if the family who occupy it are walking about on the stairs, in the hall, or in the street until they can reoccupy their dwelling? Very often the family are taken into their neighbours' rooms, and in that way spread disease.

If there were a few small houses prepared for the reception of families whose rooms were being disinfected, I think very few people would object to go into them for a day or two. In fact, they would be obliged either to use them or seek lodgings elsewhere, if there were a determination to do the disinfecting work in such a manner that the room could not be occupied for at least forty-eight hours. If such refuges were in existence there would be no objection to close houses in good repair, but known to be infected with zymotic poison, until they were subjected to thorough purification. The mere fact that small-pox, or typhus fever, or scarlatina was known to have repeatedly occurred in them, would bring them under the provisions of the 107th section of the Public Health Act, as being "in such a state as to be a nuisance or injurious to health." I do not propose at present to enter into such considerations as the cost of the refuge suggested to be erected, or its size. I merely wish to bring under the notice of the members the want of such a place, and the difficulty of dealing with houses which, though apparently in a proper sanitary state, are yet from some cause not healthy dwellings. The matter is worth considering. I do not think that the Public Health Act gives in direct terms any power to sanitary authorities to found, or contribute to the maintenance of, houses for the use of people whose tenements are being disinfected. It might be held that as they are empowered by the 100th section —also the 149th section of same Act—to "take precautions in case of any infectious disease" in lodging-houses, the precaution of providing a refuge such as that which I have indicated would be a proper one. When during times of epidemics the boards of guardians became sanitary authorities, with exceptional powers, I have no doubt they would have the power to provide refuges.

At my suggestion, the Public Health Committee have recently had constructed a moveable wooden house for the reception of families whose rooms are undergoing disinfection. Certain structural defects have rendered it unworkable; these are being remedied, and when the moveable house is in proper order it will get a fair trial, and every effort will be made to induce people to enter it.

It was unanimously resolved by the Society:—

1st. That it would be desirable to establish refuges, such as the President had indicated.

2nd. That it was necessary to temporarily close houses apparently in good repair if zymotic disease appeared frequently in them.

◆

## ON SYPHILITIC URETHRITIS, AND OTHER POINTS RELATING TO DIAGNOSIS.

By Dr. CHARLES R. DRYSDALE,

Senior Physician to the Metropolitan Free Hospital, and to the Rescue Society.

(*Continued.*)

WITH regard to the inoculations carried out by Dr. Morgan, the remark is to be made, that there was no incubation period seen in the pustules which arose in the syphilitic women who were inoculated. The pustules were not indurated at their base, nor was there any enlargement of the corresponding inguinal glands. The inoculated spot in Morgan's cases presented *at once* the aspect of suppuration, and not of adhesive inflammation; and there was no loss of the cutis as occurs in the case of local suppurating sores, the so-called *chancres*, so that it would seem, at present, that the doctrine of the diagnosis between venereal diseases is, that there is—firstly, the soft or local sore, which has nothing to do with syphilis; secondly, the purulent sore, produced by the inoculation of syphilitic or unhealthy pus on a patient affected by syphilis, and which may, if inoculated on a healthy person, cause syphilis; next the syphilitic sore, the inflammation of which is of the adhesive type, and, lastly, gonorrhœa, of two kinds, simple or inflammatory, and syphilitic urethritis and vaginitis. Instead, then, of making the subject of contagious diseases more a unity, recent researches have shown that the views of Ricord and his school, which depended on the test of inoculation, are fallacious, and that, in reality, contagious diseases of modern times are more various in their characters than has been supposed. For a time, Morgan's experiments seemed to prove that syphilis could give rise to the local soft sore, but this is, in my view, an error, according to my own oft-repeated experiments. If it should be granted, as I am convinced is the case, that vaginitis and urethritis are causes of syphilitic infection, a large number of doubtful cases will at once be capable of explanation.

Of late, a very curious remark has been made by Dr. Charles Mauriac, of Paris, with respect to the numerical proportion between the hard sore and the local chancre at the Hôpital du Midi of Paris. It was observed some twenty-five years back, at that hospital, by Dr. Puche, among the male patients, that of ten thousand sores, only one thousand nine hundred and fifty were followed by secondary symptoms; whilst at that epoch Fournier remarked that, in private practice, infecting sores were commoner than non-infecting. Of late years this ratio with respect to the frequency of venereal sores of the two varieties has been strangely reversed, syphilitic sores have become actually six times more common, in some years, in the Hôpital du Midi, than soft ones. To give one example, I quote from the pamphlet "Rareté actuelle du Chancre Simple," Paris, how that in the year ending December 31, 1875, there were 199 cases of hard sore, as against only 30 of soft sore, at that hospital. Syphilis and gonorrhœa have greatly augmented of late years in Paris, whilst soft sores have become sometimes quite rare, a fact which M. Mauriac attributes to the great extent of so-called *clandestine prostitution*. It is generally, he says, only the poorest and most careless women in Paris who contract soft sores, and these are the only women who take but little care to escape from the police.

*The Incubation of Chancre.*—In this country, owing to the confusion kept up by the views of Messrs. Paget and Hutchinson, alluded to above, the medical mind seems as yet unwilling to admit the fact that there is always—or almost always—a pretty long period of incubation, after inoculation of the poison of syphilis, before a local lesion appears. Clinical observation has, however, left not the slightest room for doubt upon this question. Diday, one of the first to write about this point, found an inoculation period of some fourteen days on an average. Cullerier, in ninety cases, a mean of sixteen days. Clerc found the time to be thirty days in different cases, and Castlenau found it to be thirty days in one case, whilst Bumpstead thought that it had been only ten days in some cases seen clinically by him.

Delhomme inoculated from a true syphilitic ulcer in one case, and there was, he alleges, an incubation of one hundred and eighty days. Rinecker, in 1852, found an incubation of twenty-five days. Baerensprung, in 1859, inoculated from a hard sore, and the incubation period was thirty-three days. Danielssen, in 1853, found the period of incubation in one case to be fourteen days. Rollet, in 1856, saw the incubation period last eighteen days; and Gibert, in 1859, remarked an incubation of nineteen days. Cullerier's case of incubation, in 1861, exhibited an incubation of fifteen days; and Fienis' case, in 1861, had an incubation of fifteen days. I might go through a number more examples to prove the length of the incubation period in true hard sore, and also in inoculations from secondary lesions, such as mucous tubercles. We may, then, admit that there is always a period of incubation after the inoculation of a syphilitic lesion which is contagious, and the knowledge of this fact is often serviceable to us in practice. To illustrate this I will narrate a case of supposed vaccino-syphilitic infection which has just come under my notice.

On December 4th of this year I visited, at the request of the Coroner for Central Middlesex, Dr. William Hardwicke, the workhouse of St. Giles, Bloomsbury, to see a child which some persons thought had died from infection of syphilis from vaccination. I saw the child in the workhouse, and made the following notes:—The infant seemed well nourished and was not emaciated; its length was 2′ 3″ from crown of head to sole of foot. It was said to have been six months old at death. There were twenty-two large and deep ulcers on the back and back of the thighs, which had eaten down through skin and cellular tissue. Many of them were an inch in diameter. There were also three similar ulcers on the abdomen, three on the right leg, and three on the left. One of the latter, on the left thigh, was the largest on the body, measuring 1½″ in length, and extending down to the level of the muscles of the front of the thigh in depth. There were four large marks of vaccination on the infant's left arm, but not the slightest induration around the superficial ulcers present in these. There were smaller ulcerations on the buttocks, but no scabs on any of the ulcers or eruptions.

I next visited the mother, who, with her husband and three children, had resided for some years in a poor little room in 26 Dudley Street, St. Giles's. From her I learnt that the infant—a little boy—had been born on June 16, 1879, and that he had always been a fine, healthy child. Dr. Faulkner, of Endell Street, had vaccinated him, she said, on November 11, 1879, and at that time the child was in perfect health. He was vaccinated from a baby that looked quite healthy, arm to arm. The infant fell ill two days after the vaccination, and on the third day a rash appeared, when she took it to Dr. Faulkner, who said it was suffering from small-pox. The child kept getting worse, and it died on Sunday, December 2nd, after much suffering, from the suppuration of the many large ulcerations covering its body.

I then called on Dr. Faulkner, the registrar of St. Giles's district and assistant public vaccinator, and he mentioned to me that the infant had been vaccinated on November 11th from a healthy child, the lymph from which had been used to vaccinate five other infants, all of which had done admirably well. The infant in question—Henry Cummings—had taken the vaccination well, for on the eighth day the vesicles were admirable, and surrounded with but little inflammation. On uncovering the child he saw a number of pustules on the back, and as there were many infants present, and he thought this was a case of small-pox, he told the mother to go away at once with the child. The evidence I gave from these data was (1) That the case was not one of small-pox, since the vaccine vesicles had matured well, and there was no eruption on the face. (2) It was not syphilis; since, firstly, there was no time for the incubation of the hard sore and no hard sore existed, and, *à fortiori*, no time for the appearance of secondary eruption. It was therefore neither a case of syphilitic infection, nor one of small-pox; but it was one of those exceedingly rare cases where a rash appears after vaccination and ulcerates. The jury gave a verdict in accordance with this opinion, which was shared by Dr. Hardwicke.

◆

**We notice in our American exchanges a patent medicine advertised under the title of Anti-lean; we presume a our enterprising cousins will be importing this precious concoction to these shores to keep pace with anti-fat.**

# Clinical Records.

## MERCER'S HOSPITAL, DUBLIN.

Under the Care of Mr. E. Stamer O'Grady.

The following four cases of reparative surgery were amongst the "discharges" during the latter part of December:—

### *Cleft Palate (Two Examples).*

*A.* A delicate little girl, æt. 5; the fissure involving the entire soft palate. After rawing the edges, the flat muscles of the palate were in great part divided by anterior section, as also were the palato-glossi, and in part the palato-pharyngei, access to these being a matter of much difficulty in consequence of largely hypertrophied tonsils. Very considerable tension was thus overcome, and the parts could be adapted nicely, four silver wire sutures, with one of silk at the apex of the uvula, kept them in perfect apposition. The silk stitch came away on the 9th day, and the others were removed after eleven days. Union obtained throughout except at the extreme upper corner, where a small hole remained, through which an ordinary probe could scarcely be passed. Ere the patient left the hospital this little perforation was touched with strong nitric acid, and it probably speedily filled in.

*B.*—A much under-sized girl, æt. 18, had three years previously been operated on with successful result, except for an oval-shaped opening (which would admit a No. 5 catheter), situate towards the anterior part of the original fissure, where it projected between the palate bones. On this occasion the osseous structure on each side was pierced by the chisel. The parts came readily together, and were easily retained so by two points of silver wire. These sutures were removed in ten days, and the patient left the hospital four days later with her cleft palate quite cured, and the lateral incision nearly healed.

### *Vesico-Vaginal Fistula (Two Examples).*

*A.* The patient, æt. 38, contracted the trouble on her ninth child. The opening was of small size, but placed high up the vagina, and imbedded in its folds in such a manner that it was difficult to find, and more so still to manipulate. Projecting the orifice on a ring-ended retractor inserted through the urethra, a spear-shaped knife effectively cut out the fistulous circle, when the wound was closed by three sutures of silver wire. These were left undisturbed for 17 days, during which the woman remained staunch, but on their removal she at once leaked again. To the very small pin-hole now remaining the actual cautery was different times applied, and on each occasion with temporary benefit. Six weeks after the first operation the second was performed in a similar way, a "harpoon" aiding materially to draw the fistula down. The silver wire sutures were removed in 13 days, but the patient was kept a fortnight longer in the hospital to test the stability of the cure.

*B.* In this individual a single operation sufficed. Patient, æt. 35, had laboured under the trouble for over three years. It occurred on her sixth child, subsequent to which she had borne two more healthy children, the *status in quo* remaining unchanged so far as could be ascertained. The hole was a small one, a little more than an inch behind the urethral orifice. The harpoon was easily inserted, and the ring of tissue around it removed. Three silver wires closed the little wound neatly. These were removed in thirteen days, union was perfect, and a week later the woman went home quite well.

In the first case a catheter was kept in for over a week after the first operation, but after the second operation, and also in the case of the patient *B*, an ordinary gum elastic catheter was kept in for only a couple of days, and its subsequent use then dispensed with.

# Transactions of Societies.

## CLINICAL SOCIETY OF LONDON.

THE last meeting of the Society was held on Friday evening, January 9th, Dr. E. H. GREENHOW, President, in the chair.

The Committee appointed by the Clinical Society to investigate "what deleterious effects follow the prolonged and continuous use of chloral in ordinary doses," reported that seventy special replies, and three printed papers had been received in reply to nearly 1,000 circulars distributed throughout the profession, followed a few months later by a second appeal, made public through the freely accorded medium of the medical press. Twenty-nine answers state that after extensive experience of chloral, in long-continued doses, no ill effects have been observed. Ten of these correspondents enjoy the special opportunities for observation afforded by asylum practice, and Mr. Curgenven, Dr. Theodore Williams, Dr. W. Squire, Dr. Buzzard, Dr. Clifford Albutt, and others, furnish cases in which chloral had been regularly and beneficially taken for periods varying from two to ten years. Before proceeding to analyse the replies received from those who had observed inconvenient effects to follow the use of chloral, the committee have thought it well to draw up a brief summary of what has already been recorded on the subject. Their special information has been arranged under the various headings of the schedule, thus :—

A.—Nervous System.

Fourteen answers record cases in which nervous debility, mental enfeeblement and convulsive seizures, appeared to follow the use of chloral; Dr. Maudsley, Dr. Clouston, and Dr. Lindsay, expressing themselves as strongly opposed to its employment in insanity.

B.—Circulatory System.

Two answers, under this heading, note some cardiac enfeeblement.

C.—Digestive System.

Six replies mention digestive disturbance as occasionally following the administration of chloral.

D.—Cutaneous.

Nine correspondents give the details of cases in which they observed itching of skin, lichenous eruption, with deep flushing of face and head following the taking of stimulants.

E.—Two replies indicate the possibility of urinary irritation being produced by chloral. Inquiry amongst some of the leading druggists of the metropolis has not established the probability that there is any remarkable abuse by the public of the facilities which they enjoy, of purchasing for themselves any quantity of chloral. The drug, it may be mentioned, is not included by the legislature amongst those, the sale of which is guarded by the name and address of the purchaser being required to be registered by the vendor. In conclusion, the Committee wish to express their regret, that, in spite of repeated appeals to individuals personally, and to the profession by circular, and through the medical press, they have failed to obtain any more definite information than that contained in the preceding report; and although the opinions expressed by numerous gentlemen of experience will, doubtless be received with the respect which is their due, the Committee would have been glad if more facts, from which definite conclusions might have been drawn, had been placed at their disposal.

Dr. BRISTOWE drew attention to the absence from the report of any expression of the views on the subject held by members of the Committee, and thought that it would have been much increased in value if it embodied the experiences of Dr. Andrew Clark and Sir William Jenner.

Dr. HEWAN had noticed an erythematous condition of the skin following the administration of chloral.

Dr. FRANCIS TAYLER recorded a case in his own experience of a gentleman, æt. 84, who had taken nightly doses of 25 to 50 grains of chloral with benefit. There were no bad symptoms, and digestion was unimpaired. The patient suffered from enlarged prostate and chronic cystitis. He had, however, noticed that semi-unconsciousness and delirium were present at night. He regretted that the report had not recorded the ages of the patients who had been observed.

Replying to the President, Dr. FARQUHARSON said he feared that detailed evidence would unduly increase the bulk of the report, but that the ages of patients would be included in it. Sir William Jenner, he added, had no personal experience to give in relation to the question, but Dr. Andrew Clark had promised the histories of five or six cases which had been under his immediate observation, and these would be incorporated in an appendix to the report already prepared.

### DR. JAMES F. GOODHART on

### A CASE OF ACUTE RHEUMATISM TREATED BY SALICYLIC ACID, AND TERMINATING FATALLY.

A girl, æt. 17, was under Dr. Goodhart's care in Guy's Hospital. She had been a servant for three years. There was a history of gout and rheumatism on the father's side, but she had always been healthy, except that she suffered from nasal polypi, and had been three times operated upon for that affection; the last time fourteen days before her fatal illness. She had had scarlatina long ago. She dated her fatal illness in some measure to the last operation for the removal of the nasal polypi, after which she felt very faint and weak, though she managed to work on for a week, when, getting up on the morning of the 17th of the month, her ankles, knees, and hips were so stiff that she went to bed again. Her back, shoulders, and arms were soon in the same condition, and the joints began to swell. She had headache and loss of appetite, but no rigors or sweating. She was treated for rheumatic fever, and got better, but relapsed in two days, and then came to the hospital. She was a dark-complexioned girl, with flushed face and bright eyes. Her tongue was red at the edges, with a white fur on the dorsum, and rather dry. The ankles, knees, wrists, and elbows, were much swollen, the skin somewhat sodden-looking, and suffused by a pinkish blush. The phalangeal joints were also swollen, and all the joints were immovable from pain. The heart at this time is described thus: Precordial dulness increased in extent; apex beat normal; slight pericardial subsultus at the base. Temperature 103°; pulse 120. Bicarbonate of potash was ordered in half-drachm doses in acetate of ammonia every three hours, with five grains of Dover's powder night and morning. Her diet consisted of three pints of milk. The next day the heart affection was more decided. The area of præcordial dulness was increased upwards to the second intercostal space, across from the sternum to the nipple and downwards to the sixth costal cartilage. The impulse was in its normal position; the action regular; the sounds were very distant and thick at the base, but there was no bruit. The lungs were normal; the urine 1·021 not albuminous. She appeared to have a good deal of præcordial distress. She was sweating freely, and the joints were still painful. The temperature had gradually fallen from 103° to 100°. The alkaline mixture was continued, but at six p.m., as she still seemed in much pain, and the temperature was rising again, though very slightly (100·4°) she was ordered fifteen grains of salicylic acid every three hours in its place. She was seen by Dr. Goodhart at nine p.m., and though still in a good deal of pain, and restless, the pulse was still at 120, and there were no particularly serious symptoms. But after this the pulse became much accelerated, reaching 160, and the patient died quietly and suddenly at 3.45 a.m. She had taken four doses of salicylic acid, sixty grains in all, the last dose three-quarters of an hour before death. She passed a restless, moaning night, but did not seem unusually ill, and she was seen by the sister of the ward, and also by Mr. Reynolds, the house-physician, at midnight, neither of whom saw any change for the worse. Nor did the nurse notice anything unusual till her death. The inspection was made by Dr. Goodhart the same afternoon. The heart weighed 9½ ounces; there was considerable eclampsia of the pericardium, and patches of recent lymph in several places. No fluid. The muscular tissue of the ventricle showed one or two points of fatty degeneration, but except these was healthy, and the ventricle was not dilated. The valves were practically healthy, although a grain or two of lymph occupied one or two points upon the mitral. The right ventricle was distended by clots of post mortem formation, and the pulmonary artery also. The latter had some resemblance to an embolic clot from being double, but it was continuous with the clot in the ventricle, and was of similar appearance; it had, therefore, in all probability formed post mortem. Of the other viscera it need only be said that the small intestine was much ecchymosed and congested, and that the joints all contained abundant yellow synovia, with coagula of yellow lymph, the knees and hips being more particularly affected. All the *bones* were normal, special search being directed to the sphenoidal, ethmoidal, and frontal sinuses in the region of the recent operation. The first appearance of the patient, her dry skin and her restlessness, augured badly for her recovery, and suggested the possible onset of hyperpyrexia; and with this prognosis in view the temperature was watched closely for some hours, but finding that it progressively fell, and that the ordinary rheumatic sweating became established, these apprehensions subsided, and the case assumed the characters of an ordinary attack of acute rheumatism of by no means severe type. Sudden death was therefore an unexpected event, and the question submitted for discussion was this: Is the result to be attributed in any degree to the salicylic acid treatment? Dr. Goodhart could not help feeling that this was possible, but he did not wish to press that opinion unduly in the face of facts which rendered the question a very open one. The several issues which seemed to him to be suggested by the case were as follows: First, an early pericarditis was present, and the muscular tissue of the left ventricle was fatty at one or two points. It is therefore possible that what, judged by the examination, was not a severe affection, may yet have been sufficient to determine the cessation of the heart's function in this particular case. Secondly, it might be suggested as just possible that between the time when she was last seen by any skilled assistant and the time of her death, nearly four hours, the temperature might have risen rapidly, and death have occurred from hyperpyrexia. Thirdly, the clot in the pulmonary artery presented unusual features, and suggested undoubtedly the existence of pulmonary embolism. It may have been an error to set aside this view in favour of another. With regard to the first it was insisted that the pericarditis and muscular change in the heart did not seem sufficient to explain sudden death; and the absence of any dilatation of the ventricle tended to corroborate this conclusion. In the second the temperature chart was one of almost progressive fall, and therefore in an unlikely condition to rise again rapidly; and thirdly, the similar appearances and the continuousness of the coagula in the right ventricle and the pulmonary artery justified the rejection of any hypothesis of embolism. There then remains to be considered the possibility of death being due to the rheumatic materies morbi, or to the sixty grains of salicylic acid which had been administered. In coming to a decision upon that point Dr. Goodhart confessed himself to be influenced not so much by this one case as by his previous experience. Acute rheumatism is no doubt a very treacherous disease, especially in young adults; but before the introduction of the salicylic acid treatment his post-mortem experience led him to the conclusion that death was associated in some cases with hyperpyrexia without obvious tissue change; in others with pleuro-pneumonia, pulmonary œdema, and *severe* cardiac complications; occasionally and comparatively rarely with acute dilatation of the heart. Since the introduction of salicylic acid he had seen three cases where death was sudden, unexpected by the physician in charge, and in which the inspection did not discover any changes in the viscera sufficient to cause death. Was it a coincidence that these cases had occurred since? All the three were girls or young women, and in all it was a first attack. Coming, as this case did, the last of three, determined him to bring it forward, as one, possibly, in which salicylic acid had acted prejudicially in a manner and with a rapidity hitherto unrecognised. This was the more necessary because the mode of death had no special symptoms attaching to it which pointed decidedly to the drug as a harmful agent, and under similar circumstances, supposing that death was caused by the drug, it is quite possible that the ill result might be attributed wrongly to other causes. Death in such cases must, if ascribed to salicylic acid, be attributed to sudden collapse and failure of the heart's action, symptoms known to be produced by salicylic acid, and some such cases of sudden collapse have already been observed and recorded by others, though perhaps rather in association with a more sudden fall of temperature. Such cases have led to the recommendation of caution in the size of the dose of the drug in cases where there should be any sign of a failing heart, or towards the end of an attack. But in the case under consideration there was no such indication for caution, moreover, caution was never overstepped; so that the result, if it be a result, could only be averted, if at all, by commencing with a very small dose and gradually increasing it. Dr. Goodhart thought that, in dealing with a drug which so quickly and so completely saturates the system, which, in some cases, and one could hardly foretell when, produces severe nervous symptoms, in others sudden collapse, this is always the wiser plan to adopt, and in many cases the smaller doses seemed to him to be all that are required for the relief of pain.

Dr. BUZZARD on

### A CASE CHARACTERISED BY SYMPTOMS OF ACUTE RHEUMATISM WHICH TERMINATED FATALLY ON THE TENTH DAY.

The patient was a previously healthy lady, aged forty-two, who got a chill coming out of the opera, on July 26th, and four days afterwards was taken with shivering "queerness" in her head, noises in her ears, and sleeplessness. When seen by Dr. Buzzard, on August 3, in consultation with her own medical attendant, Mr. Airoy, she lay in bed complaining of these symptoms, of deafness in the right ear, and imperfect hearing in the left, with constant nausea and aversion from food. The pulse had been at times as low as fifty-six, and there was much prostration. The temperature was normal, there was no paralysis, diplopia, or change in the fundus oculi; the heart sounds and breathing were normal. She had never had otorrhœa, and the deafness had only been coincident with her illness. Restorative food and remedies were prescribed. On August 5th a great change had taken place. The temperature was 103 deg. Fahr., the pulse 106, face flushed, left knee-joint swollen, very painful and powerless. There had been much sweating. Urine acid. Heart sounds normal. She was ordered fifteen grains of salicylate of soda every three hours. On August 7th, Dr. Buzzard found the temperature 99 deg., the pulse 108, the respiration 38, the heart sounds normal; the state of the lungs behind could not be ascertained. The swelling of the left knee was considerably reduced, but the right knee was now greatly swollen and painful, and also one of the finger joints. Careful inquiry and examination failed to discover any wound or sore. There was great prostration. Brandy in frequent doses was prescribed, and the salicylate ordered to be given at longer intervals. The patient sank next day. Dr. Buzzard remarked that he saw the patient upon three occasions. On the first the symptoms were entirely cerebral in character. On the second, although they pointed strongly in the direction of acute rheumatism, yet he could not help a strong feeling that the case was one of pyæmia, the cause of which, however, could not be ascertained. No doubt pyæmia did occasionally occur without any discoverable wound; he had known it happen in connection with a simple fracture, and in another case from an ulcer of intestine, found after death. In the present case all efforts to procure an autopsy were fruitless. He had not the slightest belief that the salicylate had been of injurious influence, as the patient's condition from the first was exceedingly grave. Not more than twelve doses were taken.

Dr. BRISTOWE said he could recall two cases of sudden death following acute rheumatism. In one of these the patient suddenly fainted, and died in St. Thomas's Hospital, the post-mortem showing the heart to be quite healthy. This took place long before the introduction of the salicylate treatment. The second case was observed a year or two ago, and in it also no salicylate had been administered. The post-mortem examination revealed deterioration of the muscular tissue of the heart, and death probably ensued from endocarditis, there being no other appearances of cardiac disease. He inclined to the belief that Dr. Buzzard's case was one of pyæmia. Within the last few days a patient in St. Thomas's Hospital had died suddenly, in whom the rheumatic odour of the skin, rapid pulse and acute pain had been noticed. Excision of the shoulder-joint had been performed in this case, and on post-mortem examination pus was found in quantity, together with pericarditis and pulmonary apoplexy.

Mr. HENRY LEE thought the cases read to the Society were not examples of acute rheumatism, but of such a kind as usually come within the ken of the surgeon. Frequently some skin eruption is the first indication afforded, and he remembered one case in which, though it fared well eventually, scarlet fever was diagnosed, whereas the real evil turned out to be actual blood-poisoning. He considered Dr. Goodhart's case to be one of blood-poisoning also.

Dr. HENRY GREEN did not consider that Dr. Goodhart's notes were conclusive. He had spoken of "contracted heart," but this did not necessarily imply non-alteration of the cardiac muscular tissue. He (Dr. Green) was of opinion that examination of the tissue after rigor mortis had passed away might reveal considerable muscle degeneration, spite of the contraction during the temporary rigid condition, and he could not be certain from Dr. Goodhart's description that some such chang was not present in his case.

Dr. GLOVER urged the importance of clearly describing the particular form of the drug (salicylate) employed in these cases. But he demurred to the practice of drawing definite inferences from isolated cases. He was glad to hear Dr.

Bristowe express a belief that the case reported by Dr. Buzzard was one of pyæmia.

Dr. MACLAGAN believed the case was one of acute rheumatism. Fatty degeneration, he observed, must be excited by some predisposing cause. Salicylate had been largely given in febrile and non-febrile conditions, but bad results attended its employment only in acute rheumatism. He had not, however, experienced results so bad as those encountered by Dr. Goodhart. The question to be decided was whether the fatal termination in the latter case must be attributed to the rheumatic poison or the salicylate, He felt that fatalities were more likely to occur under salicylic treatment than during any other. Myocarditis, a common attendant on acute rheumatism, is predisposed to by endocardiac inflammations, and in dealing wfth them he saw no reason to exclude the fibrous structures of the heart from participation in these changes, recognising rheumatism of the heart as of the joints. He could not assent to Dr. Goodhart's proposition that salicylates and *salicylic acid* are identical in action, and could adduce examples in proof. The influence of the poison and the action of the remedy ought to be considered in their relations to one another.

Dr. MAHOMED considered Dr. Goodhart's case to be a typical one of acute rheumatism. He had paid much attention to the sound of the heart in patients recovering from the disease, and he found that the first sound is often absent during convalescence following treatment with salicylate of soda. His experience, however, extended only over the period during which the salicylate has been in general use. Recently, on seeing a case of typhoid for which salicylate was being prescribed, he prophesied that serious evils would attend its use; and in confirmation the pulse went to 160, was thin and flickering, and all the symptons of impending death from heart failure supervened. The administration of salicylate having been discontinued, the pulse fell to below 120, and the patient subsequently made a good recovery. He felt certain that one additional dose of the drug would have caused death. He never saw the first heart-sound undergo the same change in so short a time in fever.

Dr. BARLOW inquired whether, in Dr. Buzzard's case, an examination had been made of the tympanic membrane. He thought the case might be one of internal otitis without rupture of the tympanic membrane, and followed by suppuration. The changing situation of effusion did not, he considered, militate against the case being one of pyæmia.

Dr. DOWN had found salicylate of soda produce depression in many instances, but he had not to record any death through it in his practice. He had often been compelled to discontinue giving salicylic acid, which he administered in large doses repeatedly, but the bad effects he encountered were not noticeable when he employed salicylate of soda. He doubted whether Dr. Goodhart's case was one of true rheumatic fever. In consultation he recently saw a patient, aged twenty-two, who had profuse sweating, with high temperature, but in whom the rheumatic skin odour was not present. He expressed the opinion that it was not true rheumatism, and the after-history showed him to be right, phlebitis setting in, and ultimate recovery taking place. He insisted on theimportanceof accurate diagnosis in such cases.

Dr. GOODHART defended his opinion of the case, and said that a very careful examination of it confirmed him in the belief he had recorded. The patient had been troubled with a nasal polypus, and this led him to look, but in vain, for pyæmic sources. Nevertheless, it might be an instance of obscure blood poisoning. Replying to Dr. Green, he thought that the heart might fail even when no perceptible structural changes were visible in its tissue. With respect to the varying action of the forms in which the drug under discussion exists, he could find no satisfactory records, the greatest confusion existing thereupon in books, and it was impossible to say anything definite concerning them.

In replying, Dr. BUZZARD thought Dr. Barlow's suggestion an important one, and deserving consideration. He had inquired at his first visit as to the existence of otorrhœa, but there had been none. He, however, doubted whether otitis would altogether account for the grave cerebral disturbance at first noted, with a very low pulse and a normal temperature. He was disposed to consider the case one of pyæmia, in spite of the obscurity of its causation, and the fact of the strong resemblance of the symptoms to those of acute rheumatism.

Mr. NORTON exhibited bones taken from a patient whose case was described to the Society on Nov. 14th.

# Department of Lunacy.

## THE LUNACY INQUIRY COMMISSION.

THE Blue Book containing the report of the late "Poor-law Union and Lunacy Inquiry Commission" is a work of great interest from many points of view, and seems to us to have received, both from the medical and general public, far less attention than it deserves. One of the most unfortunate characteristics of social life in Ireland is the difficulty there is in obtaining a hearing from the general public for any questions not having an obvious bearing on party politics, even when such questions relate to matters so far removed from the domain of party as the due organisation of great public charities. It is therefore not surprising that the labours of this Commission should have received little notice from newspaper readers. But the condition and the interests of those who are afflicted with the most terrible of all diseases should never be a matter of indifference to the medical profession. To members of the medical profession the unhappy class of lunatics owe every great amelioration that has taken place in their condition since the time when they were treated like the worst criminals, when they were fettered with chains and beaten with whips. The Irish physician especially may remember with pride that to the high talents and bold enthusiasm of an Irishman are due the final expulsion of cruelty and restraint from the Pharmacopœia, and the establishment on a firm basis of the rational and humane method of treating the insane.

We feel, then, that we need hardly apologise to our readers for entering at some length upon a consideration of the report before us, touching as it does upon almost every point of importance connected with the lunacy department in Ireland.

Without doubt the most important question which the Commissioners have investigated is that of the additional provision so imperatively required in Ireland for imbeciles and idiots. It has been long felt that our present asylum arrangements are insufficiont for this purpose. It will be recollected that when Mr. Gladstone introduced the Irish Church Bill some years ago he referred to the notorious deficiency under which Ireland laboured with regard to the proper maintenance of a large portion of the insane, and mentioned the surplus that would remain after disestablishmentas a fund out of which the requisite provision could be easily made. Long before that time, however, the attention of Government had frequently been directed to the incompleteness of our asylum accommodation, and the wretched condition of the insane at large. Various commissions had examined into the matter and reported upon it; but their labours were followed by no legislation, and led to no results. The reports of these older commissions not unfrequently crop out in the document before us, being sometimes referred to by the recent commissioners for purposes of comparison, and sometimes quoted to lend emphasis to conclusions at which the latter had arrived by independent investigation. It is earnestly to be desired that this last effort after improvement will not be equally inoperative for good. Some months ago Lord O'Hagan expressed his intention of not bringing forward the bill he had prepared on the subject, as he understood Government was about to take the matter up. Lord Cairns, in replying to the ex-Chancellor's remarks, gave utterance to something more than a hope that legislation would not be much longer deferred. Under these circumstances it is perhaps not going too far to expect a Government measure next session. It will be much to be deplored if the matter is allowed to drop.

It may strike our readers to inquire how it comes about that additional provision for the insane is an urgent question in Ireland, and not in other parts of the United Kingdom. The alleged fearfully rapid increase of insanity in Ireland may be regarded as at least problematic, and we believe the true reason is to be found in the poverty of the country. In England the simple and ready step of building a large number of new asylums could be immediately taken, and if more money were spent than the necessities of the case absolutely required, it would be a matter of comparatively small consequence. Unhappily the reverse holds good in Ireland. Money is hard to get, and all classes feel the necessity of economy. Money for public purposes is scarcely to be had. The cost of building an asylum is very great; indeed—considering the financial condition of the country—enormous. Again, the maintenance of an asylum, even though the Irish asylums are conducted on a far cheaper scale than the English, is a very costly affair, quite sufficiently so to be a very heavy burden on an already impoverished district. Happily in human affairs necessity, painful at first, often brings about the best results by the ingenuity it forces us to exhibit. If such changes could be effected, that all the neglected insane in the country could be brought under due supervision, and that large numbers of imbeciles and idiots whose lot is now most miserable, could be placed where they would obtain the care and attention they require, while at the same time the extreme overcrowding of our asylums was relieved, and these were thus rendered more valuable than at present as curative establishments, a great step being made in the direction of that *classification of the insane under treatment*, the lack of which is so much felt—if all this could be done at an expense comparatively trifling, the average cost per head of all the patients to be detained being very much less than it is for those now in our asylums; and this although the acute and curable cases of insanity whose treatment must always be expensive would receive no less care than at present; if, in a word, the leading recommendations of the Commissioners, whose report we are considering, were carried out, the Government would not have need to regret having studied economy, since the result would be far more beneficial to the insane than if the public money had been lavished in constructing and supporting a large number of new and costly asylums.

Be this as it may, the state of affairs that at present exists can scarcely be characterised as other than disgraceful, and surely calls loudly for legislative interference. In the 27th Report of the Inspectors of Lunatic Asylums in Ireland (referred to in the volume under review as "The Last Report") the number of lunatics of whom the Lunacy Department has cognisance is stated as amonnting to 12,373.

Besides these there are, according to the constabulary returns, 6,709 lunatics "at large;" in other words the number of lunatics at large equals rather more than half the number that is under the care of the lunacy department. (a) Of the lunatics at large 4,479 are returned by the constabulary as idiots.

Some no doubt will ask does "at large" necessarily imply "neglected?" Is not the condition of some of the lunatics mentioned in the constabulary returns what it ought to be? Of the total number 1,886 are returned as "belonging to the middle classes," and though it must not be too readily taken for granted that all these are well-cared for, yet it does not appear that legislation is urgently needed in their relief. Far otherwise is it with the unhappy individuals "belonging to the lower class." "Without," say the Commissioners, "assuming the existence of cruelty or gross neglect in the treatment of this class of poor, or without doing any injustice to the kind and charitable feeling that is ordinarily extended to them by all classes—by the humbler classes especially—it is yet certain that owing to thoughtlessness, ignorance, inability to control them, narrow resources of large and struggling families, great misery is inflicted upon these helpless beings. The Royal Commission of 1857 obtained a return of "lunatics at large" at that time, which professed to exhibit the condition as to treatment of that class. From that return it appeared that of the total number, 3,352, no fewer than 1,583 are returned as "neglected." While within the last 20 years, the number of that class has increased by more than 100 per cent.—from 3,352 to 6,709—we doubt whether there would be found to be any diminution in the proportion of those who may be still classed as "neglected."

*(To be continued.)*

## ACCOMMODATION FOR CHRONIC LUNATICS.

The magistrates of Lancashire evidently do not anticipate a speedy diminution in the insanity of that populous county, as they are providing largely increased accommodation for their pauper lunatics, who numbered altogether 7,130 on the 1st of January, 1879, of whom 4,322 were in asylums, and 2,617 in the various workhouses of the county. Some seven years ago a fourth large asylum was opened with but temporary relief to the older establishments. All the available space continuing fully occupied, and many applications for admission being refused for want of room, a special committee was appointed to investigate the subject of lunacy accommodation, and on their recommendation it was resolved at the annual general session for the county, held two years ago, that an annex for chronic harmless lunatics should be built in connection with each of the four existing asylums. Three of these annexes, with accommodation for about 2,000 inmates, are now in process of erection at a total cost of £210,000 for the buildings alone. The plans for the fourth, to contain 1,000 patients, have not yet been completed.

---

(a) Compare the English statistics. According to the Report of the Commissioners in Lunacy for 1878, there are in England and Wales 70,823 insane persons. Of these 6,000 are returned "at large or with friends (paupers)," to whom however we must add an "estimated 2,500."

The system adopted seems to possess the elements of economy, efficiency, and convenience.

Its advantages are that—

The classification of patients will be facilitated, and the transference of cases from annex to asylum, or *vice versa*, can be effected as desirable, without formalities or obstacles of any kind.

The harmless and incurable inmates may very well be maintained at less expense than when associated indiscriminately with acute and curable cases; whilst living in proximity to the asylum proper, and being under its administration, their labour and services will still be retained.

This plan differs somewhat from that adopted in Middlesex, of having large, separate workhouse asylums for quiet, incurable cases, for which a special Act of Parliament would be necessary.

## THE REPORT OF THE CHLORAL COMMITTEE.

THE Committee appointed by the Clinical Society of London to investigate the evils consequent on the use of chloral, presented their report on Friday evening last, and an abstract of the paper will be found in another part of our present issue. The best that can be said of it is, that it is unsatisfactory, meagre, and conveys scarcely any information calculated to be of service in guiding the practitioner in his decision regarding the administration of the drug. The essence of the report will be in that part of it withheld for the time, and which, as an appendix, will be available only when the whole results of the Committee's labours are embodied in the published proceedings of the Society. Under existing circumstances, seeing that the question of chloral-poisoning has lately been prominently brought before our notice, and the importance of definitely settling the position which shall in future be held by the substance, it is especially unfortunate, and withal tantalising, that so little of a really valuable nature has been the outcome of the action taken by the Clinical Society in this matter. The nett results of the investigation amount simply to a recapitulation of facts already familiar to the majority of practitioners, and briefly stateable in the conclusion that sometimes the administration of chloral is attended with danger, but that it may, as a rule, be given with no positive ill effects for an immediate consequence. What more is this, we are tempted to inquire, than might be inferred from the experience of any one, or any dozen men, who have been accustomed to resort to the prescription of chloral as a valuable and ready means of affording relief to patients who, without the assistance of some hypnotic, are debarred from the therapeutic advantages which rest confers in illness. It is not too much, surely, to expect that more, much more than this, ought to result from a prolonged consideration of such evidence as the committee should have been in possession of. In justice to the members, however, it is right to bear in mind the complaint they have issued, to the effect that they have been most inadequately assisted in the quarters where assistance could have been most efficiently rendered. We are told that the issue of a thousand circulars requesting detailed answers to certain set questions, brought back only some seventy replies; and we may conclude that fifty per cent., at least, even of these, were not of a description likely to avail the Committee to any great extent in their work. The fact itself, notwithstanding, reflects small credit on either the willingness of the profession at large to advance the progress of therapeutic science, or to respond with any alacrity to a desire for increased knowledge, the gratification of which, though for the general good, involves the personal inconvenience of themselves. The labour that they are sought to expend is but slight; the heavy part of it is the work connected with sifting and arranging the results obtained from scattered sources of information; and it cannot be too greatly regretted that an unwillingness to do the little that is demanded, when so much is offered in return, should be as widespread as the experience of the Committee in their search after data has demonstrated.

We must take exception to the manner in which the Committee has seen fit to prosecute its inquiries in part. The idea of collecting the individual experiences of a number of practitioners is certainly good: but the same cannot be said of the attempt to obtain reliable information concerning the public abuse of chloral from those interested in its increased consumption. It is the delusion of folly to base any conclusion on the evidence of chemists, in the way of determining the ill consequences of a free trade in poisonous drugs. The chemist who retails the medicine cannot possibly be a judge of the consequences, immediate or remote, that follow from its use. He is not like the medical attendant, the recipient of any personal confidences; he is solely and simply a *vendor*, and with the receipt of the amount for which he consents to supply the material he has on sale, his interest, and in the greater number of instances, his acquaintance with his customer, ceases. Moreover, holding the precarious position he does, knowing that the association with him of any facilities for the misuse of poisons is damaging to his commercial interests, he, may be easily absolved from any intention to obstruct the due progress of an investigation that may not improbably eventuate in the condemnation of his trade, and the imposition of restrictions that would seriously curtail the profits thereof. In all sincerity, possibly even believing that he is conscientiously fulfilling the requirements of his interrogators, he may yet, from his imperfect knowledge, or absolute ignorance of the fate of those who purchase his drugs, be led to yield answers that are in direct contrariety with actual facts. Much more effectual information might have been obtained by the Committee, if, instead of wasting time over the chemists, it had directed its attention to the records for the past ten years of the coroners' inquiries. A circular note addressed to every coroner in the country, asking his aid in the way of a statement, easily made from his private notes, of the number of deaths attributed in his district, within a given time, to the misuse of chloral, would have yielded a harvest rich in results eminently service able to the Committee; and we venture to think the intelligent assistance, over and above the mere acquiescence in the demand, that would have been shown by the law officers, would have done something to counterbalance the censurable apathy of the strictly professional witnesses.

The "Appendix" which is promised is to include the observations of one member of the Committee, Dr. Andrew Clark. He promises the record of five or six cases in which he directly observed the effects of chloral on the human system. Though it is a matter for congratulation that this much of actual information will be perpetuated, it is with keen regret that we recognise how little, compared with the great possibilities, has been accomplished.

The conclusions of some eminent authorities in lunacy are contained in the report, among them being Dr. Clouston, Dr. Maudsley, Dr. Lindsay, and others. The general result is against the use of chloral in cases of insanity; but even here the information is too undefined, too indeterminate, to justify anything approaching to the expression of dogmatism on the subject discussed.

It is undeniable that the question is one of vast importance, especially so since the public is concerned in a greater degree perhaps than in any other question of a similar nature. Popular favour is largely enlisted in behalf of chloralism, and if it be true—as the report certainly fails to demonstrate—that the drug is primarily noxious, then it is a paramount duty to check the destructive influence it is exerting. For this, if for no other reason, nothing but an *exhaustive* inquiry will be productive or satisfactory. And in prosecuting an inquiry that is *to be* exhaustive, recourse must be had to *every* fount of information. However laborious the work it will entail, it must be thorough, it must be full, ere any reply can be given to the question that is the basis of the whole investigation. Not only do we want to know the ages of patients to whom chloral has been given; the immediate and remote effects on them; and the condition into which its influence brings them eventually; but to give completeness to the investigation, only those cases ought to be dwelt on in which the constitutional symptoms have been observed and recorded, and the prior condition noted.

But the larger aspect is that of the influence of the drug on the bulk of the people who use it indiscriminately: and concerning this the police-court and the coroner's jury are the witnesses whose testimony will be essential and invaluable.

◆

## THE IRISH LECTURE CERTIFICATE SYSTEM.

We venture to offer to the profession our condolence upon the obviously approaching demise of this venerable —if not estimable—institution. The well-worn proverb that "Abuses die hard" has been certainly fulfilled to its utmost letter by the tenacity of life of this system; but at length we see that its component parts are manifestly falling to pieces, and that, within a year or two at most, we shall speak of the present method of granting lecture certificates in Ireland, as we did of the apprenticeship, and congratulate ourselves that we are not as other men were who tolerated and were participators in so objectionable a system.

As we have pledged ourselves to a fatal prognosis, we must detail the symptoms which lead us to despair of the continuance of the system. Some years since, it may be recollected, the Board of Trinity College, Dublin, promulgated an order to its Medical Registrar, the Rev. Dr. Haughton, that, for the future, no certificates should be recognised which emanated from a certain medical school in Dublin, because—in their opinion—those certificates were obtainable without any *bonâ fide* attendance whatever, and because, as a matter of fact, sheaves of certificates of "diligent" attendance were produced by students who could not possibly have attended even a small percentage of the lectures respecting which the certificates were issued. The disfranchisement of this school produced no practical result in the way of reform, for it never had had any considerable share in the education of Dublin University graduates, and it therefore lost nothing by being shut out from recognition of Trinity College, while the other Irish and Scotch Colleges continued, with complete serenity, to receive as proof of medical study the certificates which had been publicly branded as false.

The University of Dublin followed up this disfranchisement by the issue of an order that no certificate should be accepted for its degrees unless the grantor of it took a regular record of attendance, and would pledge himself that the student had attended at least three-fourths of the entire course. This rule is still in force, and consequently students who contemplate seeking a Dublin University medical degree are expected to hand in their cards to the lecturer at each attendance, but those who intend to enter the profession by other portals are at perfect liberty to absent themselves as often as they please, and, as a general rule, are never refused a certificate of "diligent" attendance.

Of the public exposure of the Irish certificate system it is hardly necessary to observe that neither the Irish Branch Medical Council (who were fully conversant with all the facts) nor the General Medical Council took any notice whatever until the Rev. Dr. Haughton was admitted to the Council as representative of the University of Dublin, when—at its meeting in July, 1879—we find that the following proceedings took place :—

The Rev. Dr. Haughton moved :—"That the Council do proceed to inquire what precautions are taken by the several medical authorities and corporations to secure that the certificates accepted by them from the several medical schools and hospitals guarantee a definite amount of attendance on the part of the holder on lectures, dissections, laboratory work, and hospital work ; and are not merely receipts for money paid without inquiry into the actual attendance of the holder of such certificates."

There were, he said, two classes of certificates given in the medical schools and hospitals of Dublin—one did not give any guarantee as to attendance ; in the other, it was certified that the student had attended so many lectures.

Sir James Paget said that any rules that the Council might make could be evaded. The certificate of attendance must be judged of according to the name of those signing them ; and if there were any teachers who did not act as gentlemen, but signed falsely, the blame rested with them.

Dr. Haughton's proposal was negatived by a majority of twelve—to six votes—but on the following day, on the motion of Dr. Pitman, the President asked of the Rev. Dr. Haughton the following question :—

Whether, if his knowledge were not confidential, he would give the Council the name of the medical school to which he yesterday referred, as having given untrue certificates of attendance on lectures ?

The Rev. Dr. Haughton answered that in his statement referred to in Dr. Pitman's question, he had alluded to one Dublin school and one Dublin hospital, and that he regretted that he was unable to name the school or hospital, in consequence of having obtained his knowledge *ex informatâ conscientiâ*, from the confessions of former students of Trinity College, Dublin.

It was moved by Sir William Gull, seconded by Mr. Simon, and agreed to :—

"That the Branch Council for Ireland have its attention drawn to a statement made by a member of this Council to the effect that certificates of attendance have been issued in a Dublin school to students who have not given such attendance, and that the Branch Council be requested to inquire into this matter, and to report thereon to this Council at its next meeting."

We believe that the Branch Council has—in pursuance of this order—addressed a letter to Dublin schools and hospitals, requesting information as to the method adopted of checking the attendance of students, and that it has, within the past week, directed a second request for such information to those schools and hospitals which have proved reticent.

Still one other symptom of the dissolution of the Irish certificate system has presented itself within a few weeks which—by itself—is worthy of note as an illustration of the results of the most disreputable method of procedure Finding that neither a personal presence at lectures or hospital, nor medical study of any sort, was essential to the obtaining of certificates of "diligent" attendance, a large number of young men have been encouraged to enter the medical profession without any real medical study whatever. These *soi-disant* students are engaged for the entire working day, and often for the evening also, behind counters in shops, banks, and offices, and their system has been to enter their names for lectures and hospital at the beginning of each session to occupy the three years of their supposed study in putting together the money for the subsequent purchase of the certificates, and, at the end, to resign their employment, buy up the documents, and devote themselves ardently to six months' grinding, and to the passing of their examination. Those examinations having, of late years, somewhat improved in severity, these young men have found an increasing difficulty in getting through them without any knowledge, and they have, therefore, moved the managers of certain schools—and of the Carmichael College amongst others—to provide them with courses of evening lectures, which that school announced by public advertisement its intention to do. Thereupon the Council of the Irish College of Surgeons was moved to adopt, and did adopt, the following resolution deprecatory of the proposed system.

"That in the opinion of this Council, the system about to be introduced into two of the Dublin schools of medicine, as stated in the public advertisement, of giving courses of lectures late in the evening and at night, in addition to those given during the day, is objectionable, and should not be put in practice."

This resolution having been communicated to the Carmichael College, a reply was returned which was also—in substance—communicated by the Carmichael College to the General Medical Council, and appears *in extenso* in their minutes for Nov. 28, 1879. It contains the following passages :—

"It is a notorious fact that a considerable number of the medical students in Dublin are employed as clerks, assistants, &c., in such a way as to render regular attendance on lectures in the day time an impossibility.

"It is not for the directors to say how such students obtain their certificates. The only official information they have on the subject is the following :—

"1. They know that students who would otherwise join their school are deterred from doing so, owing to their rule which requires attendance on half of each course of lectures.

"2. A request was forwarded to them, through one of their lecturers, from some students that courses of evening lectures should be established. In this request it was stated that the students in question were desirous of availing themselves of the lecture system ; that they could not attend in the day time ; that if we did not establish evening lectures they would have to go to a school that did not require attendance ; and that they considered it a great hardship to have to pay for lectures which they could not possibly attend."

After referring to the action of the Irish College of Surgeons, the letter proceeds :—"It has been stated that men in business ought not to be encouraged to become medical students, and the authority of the General Medical Council, in recommending that four years should be spent exclusively in the study of medicine, has been urged in support of this view. In both statements the directors most fully concur ; but they fail to see, as men in business *are* permitted to be medical students, that it is not a great deal better for them to have the opportunity of gaining such knowledge as the directors believe can only be obtained from lectures than that they should not."

The circumstances to which we have referred, are those upon which we base our prognosis, that the monstrous system current in Ireland of certifying the "diligent" study of students, whom the certifier never saw, and possibly never heard of, has at length come to an end, and that, with it, tumbles down the enormous edifice of fee-paid lectures, which has been erected by teachers upon the shoulders of over-burthened students.

It seems evident that the system can no longer be kept quiet or ignored. It has been publicly denounced by the representative of the University of Dublin in his place in the Medical Council. It is to be the subject of a special report by the Irish Branch to the next meeting of the General Council. It is submitted directly and officially for the opinion of the Council by the Carmichael College, and, without doubt, it will be the subject of investigation by the Select Committee of the House of Commons.

Having already, on many occasions, laid bare the abuses of the Irish certificate system, it remains for us only to add our testimony to that of Dr. Haughton and of Dr. Reuben Harvey, the Secretary of the Carmichael College, and to assure those whom it may concern, that the statements made by those gentleman are strictly true, and even fall far short of the whole truth.

It is unhappily necessary to confess that under the existing system the fulfilment of a curriculum of study, as testified by the signatures of teachers, is in Ireland, at least, absolutely worthless as proof that the student has learned anything. The certificates that he has "diligently" attended certain courses of lectures, and months of clinical instruction, are, in many instances, and may be in any particular instance, altogether unreliable, and if they were to be read literally, would be nothing less than a series of documentary falsehoods. We are bound to do the teachers who sign them the justice to say that—in the great majority they are incapable of deliberately making a statement which they do not know to be true, and that they are induced to testify as to the "diligent" attendance of an unvouched student, because they hold that a certificate has ceased to be what it professes to be, and that is, as Dr. Haughton said, merely a testimonium that the student has paid for instruction, and that it is at his disposal if he pleases to avail himself of it. Viewed in any other light than this, certificates must be stigmatised as a fraud—disgraceful to the person attaching his name to them, and to the student who accepts them, and doubly disgraceful to the system which has countenanced such an imposition. That certificates of diligent attendance are regarded by Dublin teachers simply as receipts for fees is manifest from the fact within our knowledge that, some years since, a bundle of such certificates were recognised as admitting a number of candidates to examination, although they were signed by a lecturer who was not in any way connected with the school in question at the time when the lectures purported to have been delivered, and who, therefore, was in the position of certifying to the diligent attendance of students whom he never saw upon lectures which he never delivered. As we have said, on a former occasion, instances might be quoted in which students have presented the usual evidence of having "diligently" fulfilled the four years of their curriculum of study, and obtained their diplomas almost with honour after the usual examinations, though they had been engaged behind desks in banks or counting houses for the entire working day during which their lectures and hospital studies were supposed to have been attended, and the career of students thus licensed to kill or cure might be followed by their appointment within a few months, as hospital surgeons and clinical teachers, in which capacity they, for the first time, commenced the true study of their profession. It is a well-known practice for needy students to undertake service behind an apothecary's counter, and to continue in that employment steadily and regularly engaged in dispensing and attending to the shop business until within a few months of the time of their examination, at which period, having saved up by their service behind the counter a sum sufficient to pay for their certificates of "diligent" attendance at hospitals and lectures, and for the services of an experienced "grinder," they leave the service of the apothecary, submit themselves to a hasty "cramming," and are in due time impressed with the stamp of medical compentency by a licensing corporation. Certificates have, however this much value, that they do testify truthfully that the student, having paid for the courses of his instruction, has at least had the opportunity of learning afforded to him, and has, so far, had an inducement afforded to him to avail himself of that instruction. We do not for a moment mean to infer that certificates do not frequently represent work done, and valuable instruction given, but we assert that they are readily obtainable by the idle and ignorant students, and are no proof of anyone's assiduity or capability.

## Notes on Current Topics.

### Royal College of Physicians of London.

We have been furnished with a programme of the lecture arrangements at the College for the present year. It is as follows:—The Gulstonian lectures will be delivered by Dr. Gowers, on Feb. 20, 25, and 27, the subject chosen being "Epilepsy;" the Croonian lectures will be delivered by Dr. Cayley, on March 3, 5, and 10, subject, "Some Points in the Pathology and Treatment of Typhoid Fever;' the Lumleian lectures will be delivered by Dr. W. Roberts, on March 12, 17, and 19, subject, "Researches on the Digestive Ferments and the Preparation and Use of Artificially Digested Food." The time of delivery is the same in every case, namely, 5 o'clock, and the days of the week are likewise the same, Wednesdays and Fridays. Members of the profession are admitted on presentation of their card.

### The Health of Dublin.

The deaths registered in the Dublin district during the week ending the 3rd January, represent an annual mortality of 43·3 in every 1,000 of the population. The death-rate in eight large towns of Ireland (including Dublin) last week was 39·8. In twenty large English towns inclusive of London (in which the rate was 31·5), 29·1; in Glasgow 22·9; and in Edinburgh 24·2. Fifty-three deaths from zymotic diseases were registered, being 5 less than in the preceding week, but 21 over the average number in the last week of the last ten years; they comprise 4 from small-pox, 13 from measles, 15 from scarlatina, 2 from croup, 6 from whooping-cough, 3 from fever, 3 from diarrhœa, &c. The registered deaths from small-pox (4) are 1 less than in the week ending 27th ult., but the number of new cases of the disease admitted into the Dublin hospitals rose from 17 to 36. The mortality from scarlatina was exceeded in only one week during the year 1879, namely, in that ending 15th November, when 19 deaths were registered. The deaths from this disease have been 9, 9, 13, 6, 8, 19, 15, 15, 12, 14, 10, 9, 15, respectively, for the last thirteen weeks.

### Frozen Medicines.

IT is asserted by Dr. Edwyn Andrew, in the *New York Medical Record*, that many drugs can be given with superior advantage by first freezing them. Antiseptic, astringent, anti-emetic, and nauseous medicines come under this head, and can be combined with ice without difficulty. An especially good feature of this plan is in its affording a possibility of the stomach's retaining medicines which it would reject when given in ordinary ways.

### Multiple Licensing in America.

THE Censors of the Medical Society of the county of New York, in a report on this subject, observe—"In the whole of Great Britain there are, we believe, only about twenty licensing bodies, while in this State alone there are probably between 100 and 150. In this county there are at least twelve bodies that habitually exercise this power."

### Medical Men and Coroners' Courts.

AN adjourned meeting was held last evening at the Coroner's Court, St. Pancras, to consider the present relation of medical men with the Coroner's Court. As the subject is one of great importance, we propose devoting space to a discussion of the question, and the results arrived at, in our next issue. At the former meeting held just before Christmas nothing definite was arrived at. A proposal was made that a "referee" be appointed to superintend all post-mortem examinations, who should receive a fixed fee of one guinea for each occasion. The objections to this plan are obvious, and we expect to see them dwelt on at the meeting to-night.

### The London Hospital.

ON Tuesday, Wednesday, and Thursday of last week, a series of dramatic representations took place in the large room of the Nursing Home at the London Hospital. The performances were conducted by members of the resident staff, and the hospital students, aided by certain of the sisters on the nursing staff. The result was highly successful, and redounded to the credit of the stage manager, Mr. W. Blagdon Richards, under whose supervision the whole took place. The example set by the London is one that might be followed with advantage by other of the hospitals in town. It shows that a spirit of good will exists between the several officers of the institution, and besides, a readiness on the part of the governing officials to lend a pleasant variety to the monotonous routine of hospital duty. We venture to think the liberal spirit that pervades the council of the Whitechapel charity is as conducive to good, honest work, and leads to as much hearty assiduity, as the petty ruling of other places which permits not the slightest relaxation from the strictest routine.

### A New Remedy.

WITH the coming summer we are threatened with the introduction of a new remedy, for which is claimed a wonderful efficacy in cystic and nephritic affections. The stigmata of maize, or "corn-silk," is the substance which, for our sins, is to be added to the list of new drugs already unconscionably longer than the list of benefits derived from their use. The mode of administration of the maize stigmata is to be the extract or syrup, the decoction being "unreliable." The results already obtained with the drug are rapid suppression of the painful symptoms of vesical catarrh and chronic cystitis. In cystitis subsequent to gonorrhœa, or when traumatic in origin, though the medicine produces marked diuresis, it excites increased pain. It may possibly be that the stigmata of maize do contain a product that will prove of therapeutic value, but the experience of recent so-called "new remedies" is not encouraging to the hopeful.

### Clinical Society of London.

THE annual meeting of the Clinical Society of London took place on Friday evening, when the secretary and treasurer presented their reports for the year 1879. Both officers' accounts of the progress and position of the Society are highly encouraging; and one subject of congratulation to the members is the fact that it has become necessary to invest the property of the Society in the names of trustees appointed for its custody. As the twelfth volume of "Transactions," recently issued, indicates, the Clinical Society is in the thirteenth year of its existence; and though that is but a short time compared with the life of some other associations, it would be difficult to point to any one which had in the same period done more or better work, work of eminent value in advancing the service and practice of medicine and surgery. With a very handsome nucleus of capital, it may be prognosticated that the future of the Clinical Society will in no way reflect on its early years. It has every appearance of a vigorous life, and with this the assurance of excellent work.

### Sir Joseph Fayrer on Typhoid.

IN his presidential address to the Epidemiological Society, Sir Joseph Fayrer expressed himself as having little doubt that the typhoid fever contracted by our soldiers in India is exactly identical with the form of the disease which might be contracted in any big town at home, from a water-closet, drain, sewer, well, or milk-can. But, he continues, "I believe also that perhaps as frequently, or more so, it is not; and this I believe not in regard to young European soldiers only, but of the whole population of India. In short, I am, and long have been, of the opinion that a form of fever exactly like European typhoid, except in its etiology, exists in India and other hot and malarious countries, and that it is due to climatic cause, not to filth or specific causes, such as give rise to it in England and elsewhere, and recent reports from India and other parts of the world seem to show that this view is gaining ground." He carefully asserts, however, that he does not dispute the existence of genuine *filth* typhoid in India. The official returns, which cannot be gainsaid, and his own experience, alike leave him in no doubt about it.

## A Sad Ending to an Army Surgeon.

The *Indian Herald* narrates the following melancholy circumstances which attended the death of the late Dr. Dumbleton, who was a young surgeon from St. Bartholomew's Hospital, who only arrived in India to join the Indian Medical Service last March, and was recently ordered to proceed to Peshawur. From Peshawur Dr. Dumbleton proceeded in medical charge of a draught *en route* to join the Kurrum Valley Force. Being but an indifferent horseman he was much galled by his long ride; in addition he suffered from a severe attack of fever, and when on the march the detachment met the 13th Bengal Lancers. The medical officer in charge of that regiment told Dr. Dumbleton that he was in an utterly unfit state of health to proceed; he also provided him with a pair of drawers. Thus relieved poor Dr. Dumbleton managed to push on to Ali Kheyl. Here he went to a staff officer, who saw from his miserable appearance that he was quite unfit to go further, and he said that he would make arrangements for some other surgeon to go on with the detachment. The poor lad went to his tent, threw himself down in his clothes, and fell asleep. Early next morning an officer of his detachment went to his tent and said, "Come, Dumbleton, it is time to get up; we must be off." Dr. Dumbleton replied that he was utterly unfit to go on, as he was so ill, and that arrangements had been made for another surgeon to take his place, and the officer left him. Dr. Dumbleton appears to have been a very sensitive young fellow, and he feared he should be accused of pretending to be worse than he really was. After a short time the officer of his detachment returned, saying that no arrangement had been made for another surgeon to go with them, that they could not march without one, and that go he must. Dr. Dumbleton replied that he could go no further, adding, "By God, I am not shamming," and the officer again left Dr. Dumbleton in his tent. He had only gone a few yards when he heard the report of a pistol, and rushing back to Dr. Dumbleton's tent, he found the poor young fellow dead with a revolver beside him—harassed to death.

## The Harveian Society's Soiree.

The annual *conversazione* of the Harveian Society took place last Thursday evening, when Mr. Henry Power assumed the presidential office. During the evening Mr. James Samuelson exhibited and described Rhodes' audiphone, a Transatlantic instrument for the purpose of aiding the acoustic perceptions of deaf people. The result of the experiments made at the *soirée* were, however, not encouraging to the inventor, for the general impression left by them was that the audiphone gave but little assistance of the nature claimed for it. It resembles an ordinary hand fire-screen, made of thin varnished metal, and mounted on a handle. By means of a string attached to the free end of the plate, and passing through a groove in the handle, the plate can be curved any desired extent, and being fixed in the position it is to maintain, is held lightly grasped between the teeth. The vibration of the plate, consonant with the utterances of the speaker, are then communicated through the teeth and the bones of the skull to the auditory apparatus and sensorium, and thus impressions of sounds are transmitted when the natural channel of reception is closed to them. The invention will very probably yield good fruit in the future, but it cannot be said that its exhibition on Thursday was a successful demonstration of its value.

A large number of valuable works of art, instruments, curiosities, &c., were exhibited at the *soirée*, especially some microscopical slides contributed by Mr. D'Arcy Power, Mr. Malcolm Morris, and Mr. Walter Pye. Among these were sections of elephantiasic skin that were peculiarly interesting by showing the hypertrophied structures with remarkable clearness.

## Great Expectations.

Last week the new Lord Mayor of Dublin, Mr. Gray M.P., was installed with the usual ceremonies. When the investiture was completed at the City Hall, and the Lord Mayor had taken the chair, he returned thanks for the honour paid to him, and referred at some length to local affairs; amongst other things he announced that the Council had taken considerable trouble for the purpose of carrying out great public improvements in Dublin. They contemplated expending during this year a sum of no less than £200,000 in public works; about £100,000 would be spent in re-paving the city, £35,000 in the carrying out of the provisions of the Artisans' Dwellings Act, £30,000 in improving the sewers, and other sums in the erection of abattoirs and similar necessary works. He further alluded to the large powers conferred upon the local bodies by the Public Health Act and the Municipal Privileges Act, which he thought would greatly tend to the ultimate improvement of the city. Dublin citizens will, no doubt, be grateful to the Lord Mayor and Corporation for the privilege of paying £200,000 in addition to their perennial taxation of over 9s. in the £1. But why will the Lord Mayor not promise a little energy in the reconstruction of tenement houses (which would not cost a shilling)? and is he not aware that the Corporation has possessed its sanitary powers ever since 1874, but has declined to use them? We pause for his Lordship's replies.

## The Purposes of Contagious Hospitals.

There was an animated discussion at the Metropolitan Asylums Board on Saturday last, the first meeting of the year, on the important question of the right of any public body to devote a building which has been once erected and devoted to the purposes of a small-pox hospital to the reception of patients suffering from other diseases. This arose in consequence of the reception of a letter from the guardians of the Hackney Union, complaining that the Homerton Hospital had been so appro priated. The Hackney Guardians stated that they had been acquainted with the circumstances which had induced the managers to utilise the small-pox hospital at Homerton for treatment of patients suffering from enteric fever. They were, however, apprised that it was the opinion of the medical profession generally that a hospital once appropriated to the reception of persons suffering from small-pox should be retained solely for that purpose. The guardians therefore considered, notwithstanding the explanation of the managers, that steps should be at once taken to make ready the Homerton Small-pox Hospital for the reception and treatment of patients suffering from small-pox, and not delayed until the pressure for accommodation of fever patients had subsided, as suggested by the managers.

Dr. Brewer presided at this meeting, which was fully attended, and after a full consideration of the subject and its applicability at the present moment, notice of motion was ultimately given by Sir F. H. Currie, calling upon the managers to reinstate with the least possible delay the Homerton and Stockwell Hospitals for Small-pox to the purposes for which they were erected, and that it be referred to the chairman of the hospitals committee to make the necessary arrangements.

This is a most important question, and if decided, as doubtless it will be, in accordance with the opinions expressed generally by the members of the Board, its influence will be quickly felt throughout the country.

## St. Virchow's Well.

THAT the great pathologist and opponent of dogmatic belief should himself become a miracle-worker is a funny satire. Yet the *Philadelphia Reporter* says that such is the tact. When he went last spring to look at Dr. Schliemann's diggings at old Troy, the rumour soon spread that he was a renowned healer of disease. Consequently, sick and infirm people flocked in daily increasing numbers to Hissarlik, from far and wide. There are no roads and no vehicles. So people came on foot, or on horseback, or riding on asses; even women coming thus from a long distance. Very infirm people were brought in great baskets slung across a horse's back, sometimes one on each side by way of balance. The patients used to range themselves in a long row, opposite the wooden hut in which Virchow lodged, each waiting patiently until his or her turn came.

But the joke remains to be told. While there Virchow had a well dug in the old bed of a stream, now dry, to obtain good water. Since he left, Dr. Schliemann writes that the inhabitants "regard the excavation and spring with veneration, and have fenced it around with stones. The spring is called 'the doctor's well,' and magical virtue is ascribed to it. Every one comes to draw water from it."

## Hydrobromic Ether as an Anæsthetic.

THE experiments of Rabuteau on the lower animals to demonstrate the anæsthetic properties of hydrobromic ether, have, says the *Boston Medical and Surgical Journal*, led Dr. Turnbull, of Philadelphia, to employ it on the human subject. His successful results have induced others to make trial of the substance, and Dr. Levis has used it for large operations at the Pennsylvania Hospital with gratifying success. Four cases are recorded, viz., amputation of the fore-arm at the upper third; perineal section for stricture of urethra; resection of stump after former amputation of the arm; and in a case of fracture of both legs, where it was administered in order that a careful examination might be made, and tenotomy be performed. The after-effects of the inhalation are less severe than those following the use of chloroform, and the return to consciousness very much more rapid. Though its claims to be admitted into general use are said to be strong, it is admitted that it needs more careful observation to establish it firmly as a safe anæsthetic in general surgery.

THE Adult Imbecile Asylum at Darenth in Kent, is in want of a medical superintendent. Applications for the post should be sent in before the 17th inst. to the offices of the Metropolitan District Asylums Board, 37 Norfolk Street, Strand.

AT the annual meeting of the Sheffield Literary and Philosophical Society held last week, Dr. Whiteside Hime, Medical Officer to the Sheffield Sanitary Authority, was elected president for the ensuing year.

BY telegraph from Afghanistan we learn that owing to the cold and exposure there is much sickness prevalent among our troops, both native and European. There are now upwards of one hundred and eighty cases of pneumonia in hospital.

WE learn from the local papers that a Derby chemist who was in the habit of taking a mixture containing prussic acid to relieve him from spasms, on his return home from a party early on Wednesday morning last week, put too much of the poison into his mixture, and the result was his death within a few hours.

THE next meeting of the Society of Medical Officers of Health will be held on Friday, January 16, at 7.30 p.m., at 1 Adam Street, Adelphi, when a paper will be read by Dr. Tatham, Salford, "On certain Reforms which appear desirable in the Statistical Reports of Medical Officers of Health."

VERY sad accounts of the condition of the populations come from Italy, especially the Neapolitan provinces. Fever has become epidemic over large districts; in a population of sixty-one thousand six hundred and seventeen, the sick amount to thirty-two thousand five hundred and eighty-seven; the deaths of a zymotic character, from the middle of July to the middle of December, were three thousand four hundred and twenty-three.

DR. CURTIS, Professor of Natural Philosophy and Registrar in the Queen's College, Galway, has been appointed an Assistant Paid Commissioner of Intermediate Education in Ireland. Dr. Curtis has been an Examiner for Degrees in the Queen's University in Ireland for nearly twenty years, and is also a member of the Endowed

School Commission, and by his promotion the Professorship in the Galway College becomes vacant.

THE *Medical Record* says of the doctors in Memphis in 1878:—All the homœopaths ran away when the plague existed. Of the forty-six regulars, ten ran away; of the thirty-six remaining, twenty-eight were attacked by the fever and fourteen died; eight had already had the disease and were not attacked at all..

ALTHOUGH the temperature in the United Kingdom has risen considerably during the past fortnight the death rate is, nevertheless, much above the average. Last week the rates of mortality per 1,000 were—Sunderland 20, Portsmouth 21, Oldham 22, Norwich 23, Bradford 23, Newcastle-upon-Tyne 23, Sheffield 23, Glasgow 23, Wolverhampton 24, Leicester 24, Edinburgh 24, Hull 26, Birmingham 27, Bristol 28, Manchester 28, Leeds 28, Nottingham 30, Liverpool 31, Brighton 31, London 32, Salford 32, Plymouth 35, and the highest rate of all Dublin 43.

IN the principal foreign cities the rates of mortality, according to the most recent official weekly returns, were—in Calcutta 36, Bombay 35, Madras 40; Paris 33; Geneva 19; Brussels 42; Amsterdam 33, Rotterdam 33, The Hague 36; Copenhagen 24; Stockholm 19; Christiania 12; St. Petersburgh 41; Berlin 24, Hamburg 29, Dresden 21, Breslau 27, Munich 32; Vienna 28; Buda-Pesth 32; Rome 42, Naples 27, Turin 29; Alexandria 40; New York 23 per 1,000 of the population. Small-pox caused 56 deaths in Paris.

THE death-rate from the seven principal zymotic diseases ranged from 0·0 and 0·8 in Wolverhampton and Portsmouth, to 5·3 in Liverpool, 7·3 in Dublin, and 9·1 in Plymouth. Scarlet fever showed the largest proportional fatality in Newcastle-upon-Tyne, Leicester, Dublin, and Bristol; measles in Plymouth, Hull, Liverpool, Bristol, and Nottingham; and whooping-cough in Salford, Newcastle-upon-Tyne, and London. Of the 27 deaths from diphtheria, 16 occurred in London, 3 in Birmingham, 3 in Liverpool, and 3 in Manchester. Small-pox caused 4 more deaths in London and Dublin, but not one in any of the other large towns.

LAST week Mr. H. Trimen, a young surgeon, was the victim of a cruel robbery in London. Having obtained a colonial appointment, he sold the few bonds he possessed for £300; this he deposited in a desk in the bed-room occupied by him at his chambers in Craven Street, Strand. A day or two later, when about to leave England, he discovered that the whole sum had been abstracted. He at once gave notice to the police, and one of the notes was traced to a waiter engaged on the premises. This man, a German, was at once arrested and committed for trial on Saturday last. In the meantime Mr. Trimen will have to remain in England to prosecute, and will probably lose his appointment in consequence.

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

HEALTH OF EDINBURGH.—For the week ending Saturday the 3rd inst., the deaths in Edinburgh rose from 90 to 101, giving a death-rate of 24 per 1,000. No deaths were recorded from fever, diphtheria, or small-pox, and the zymotic mortality was otherwise small.

THE MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending Saturday, the 3rd inst., were at the rate of 23 per 1,000 per annum against 27 in the preceding week, and 30, 29, and 28 in the corresponding periods of 1879, 1878, and 1877. The rate for the whole year ending 31st December has been the lowest on record in Glasgow, being 22 per 1,000. The rate for 1878 was 25.

DEATH FROM POISONING BY ARSENIC IN GREENOCK.—On the evening of the 5th inst. the wife of a nurseryman died in the Greenock Infirmary from the effects of oxide of arsenic. Antidotes were given, and every effort made to relieve the unfortunate woman, but without success. How the arsenic was taken does not transpire.

THE LADIES AND THE MANAGERS OF THE EDINBURGH ROYAL INFIRMARY.—At a meeting of the contributors to the Edinburgh Royal Infirmary, held on the 5th inst., a discussion took place on the proposal to appoint two ladies to the Board of Management. For the six vacancies which the contributors are entitled to fill, six gentlemen were nominated by Mr. David Smith, W.S., and seconded by Sir James Falshaw. The two lady candidates were then proposed by Treasurer Harrison and seconded by Mr. Charles Cowan. Some argument took place as to whether one of the ladies nominated, not being a member of the corporation, was eligible for election. Mr. Hope, D.K.S., the contributors' law-agent, was of opinion that she was, in these circumstances, disqualified, but the final settlement of this question was postponed till the result of the voting should have been ascertained. After some discussion, scrutineers were appointed to receive the votes, which were taken by voting papers. The result was 240 votes were given for the return of the gentlemen alone, 169 for ladies, and 53 persons gave in voting papers for both gentlemen and ladies.

GLASGOW ROYAL INFIRMARY APPOINTMENT.—At a meeting of the directors of the Royal Infirmary of Glasgow, held on the 5th inst., Dr. Johnstone Macfie was appointed to the office of Aural Surgeon to the Hospital, and Lecturer on Aural Surgery in the Medical School, in room of Dr. Cassells resigned.

REGISTRAR-GENERAL'S RETURNS.—According to the weekly return of births, deaths, and marriages for Scotland it appears that the death-rate for the week ending 3rd January, 1880, was 21·9 per 1,000 of estimated population. This rate is 7·7 under that for the corresponding week of last year, and 3·2 under that for the week ending 27th December. The lowest mortality was recorded in Aberdeen—viz., 15·1—and the highest in Paisley—viz., 32·9. The mortality from the seven most familiar zymotic diseases was at the rate of 3·0 per 1,000, being a slight decrease on the rate for last week. Whooping-cough continues the most prevalent of these diseases. Acute diseases of the chest caused 169 deaths, being 40 under the number recorded during the last week of 1879. The mean temperature was 42·6, being 2·9 above that of the week immediately preceding, and 8·1 above that of the corresponding week of 1879.

**Glasgow Maternity Hospital.**—Dr. Brock, formerly out-door physician-accoucheur, has been elected an Assistant-Physician to this hospital, in room of Dr. S. Sloan, who was recently made physician.

## Literature.

### THE IRISH MEDICAL DIRECTORY.

The ninth yearly issue of this work is just out. It increases in obesity by age and has received an addition of about forty pages to its size since its last issue. As to its value as a reference record of the medical men resident in Ireland some judgment may be formed by reference to the obituary pages, in which may be found the names of our brethren of whose demise few would be aware save those whose knowledge is local. The same observation applies to the migration of the members of our profession and their consequent changes of public office, which would certainly escape the notice of any compiler who was not in daily observation of their comings and goings. The beneficial effect of this intimate acquaintance with Irish medical movements which the Editors of this Directory possess is manifest on reference to its pages, where will be found, but very seldom in comparison to its frequency in other Directories, the entry, "address unknown," or the name of a deceased or emigrated doctor. The accuracy of this part of the work is the more remarkable considering the absolute impossibility of eliciting an answer from some medical men to any letter addressed to them, and. on the whole, it may be truthfully said that there is no list extant of the Irish profession which at all approaches this in reliability. As to the other contents of the book, we find an equal difficulty in saying what it does contain and what it does not—the former, because an epitome of its contents would include almost every subject in which the profession in Ireland is interested—the latter, because we should not find it easy to hit upon an item of such information which it does not contain : Poor Law, Lunacy, Registration, Army, Navy, Charitable, Educational, Constabulary, Admiralty, Factory, Prisons, and all other public medical services in Ireland are supplied with exhaustive information special to themselves and of much interest to the general reader.

The specialities of the issue for 1880, as far as we observe them, are—*a.* The New Army Warrant ; *b.* The New Prison Rules ; *c.* The Habitual Drunkards Act ; *d.* The New Vaccination Act ; *e.* The Dispensary Houses Act ; *f.* The Prisons Act ; *g.* The Factory Act ; *h.* The Sale of Poison and Drug Adulteration Acts, and the new Sanitary Orders of the L. G. B. If these items be added to the connected details of former Directories we think we are entitled to say that nothing is omitted. The book is issued with commendable punctuality and in a most satisfactory form as regards workmanship, and, we should suppose, has come to be indispensable both to the profession and the public .

## Correspondence.

### THE MORTALITY OF ROME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—May I ask from whom you get the figures published in your excellent medical journal concerning the weekly returns of the rate of mortality in the city of Rome ?

With your permission I will quote the statistics for two months from your columns—

Weekly mortality in Rome per 1,000 inhabitants.

| | |
|---|---|
| September 10 | 29 |
| September 17 | 27 |
| October 1 | 25 |
| October 8 | 29 |
| October 15 | 30 |
| October 22 | 31 |
| October 29 | 35 |
| November 5 | 30 |
| Total | 237 |

The total of those eight weeks here quoted is 237, which would give an average mortality of 30 per 1,000 inhabitants. As these figures did not agree with my notions, I applied to our *Direction of Statistics and Stato Civile* for an authenticated note of the rate of mortality of the corresponding weeks, and here is a copy of it—

Mortality in Rome per 1,000.

| | |
|---|---|
| Week ending the 6th September | 21·3 |
| " 13th September | 20·8 |
| " 20th September | 25·3 |
| " 27th September | 22·4 |
| " 4th October | 24·7 |
| " 11th October | 28·9 |
| " 18th October | 22·8 |
| " 23rd October | 29·1 |
| " 1st November | 23·0 |
| " 8th November | 26·2 |
| Total | 239·5 |

Medium average of the 10 weeks, 23·95. The actual rate of mortality during that time was therefore 24, not 30, as stated in your paper ; or in other words, you give to the city of Rome one-fifth higher mortality than the official returns.

I would have taken no notice of the outcry against the sanitary condition of Rome raised in England and abroad generally, but curiously, all these assertions about the pestiferous state of Rome have been since the time Rome ceased to be under Papal Government, and in the hands of the Government of Italy ! It is an undeniable fact that Rome during the previous administration was kept in such a filthy condition as to be worthy the appellation of "pig-sty." Now, Rome has grown, under its municipal administration, one of the cleanest cities of Europe. If it be true, that its sanitary conditions are now so bad, the natural inference would be, that the attention given to drainage, to cleanliness, to the removal of nuisances, and to the hygienic measures recommended by medical science, are evidently injurious to the health of the population. In order to ascertain the truth of these reports, I applied again to the Statistical Office.

No regular statistical returns were published or kept in the time of the Papal Government, and I cannot, therefore, make a comparison with those years and the present returns ; but as soon as the Italian administration took Rome, the Statistical Office was founded, and the *Stato Civile* ordered to be kept by the municipality with the utmost diligence and strictness, under the control of the judicial power, as the office forms the ground upon which is based the succession to property and the recruiting of the army.

The first year of the Italian occupation, and of the introduction of the statistical returns, was 1871, and the rate of mortality was reckoned at 31·6 per 1,000 inhabitants in that year. However, some objections may be raised about the returns of that first year, and, therefore, I will not take notice of it. Here is the account of the rate of mortality of the following years—

| Years. | Per 1,000 inhabitants. |
|---|---|
| 1872 | 37·1 |
| 1873 | 29·3 |
| 1874 | 26·6 |
| 1875 | 30·3 |
| 1876 | 28·3 |
| 1877 | 23·4 |
| 1878 | 23·0 |

In order to institute a comparison between the state of health of Rome, when the new administration entered, upon its duties, and that which succeeded, I will put in comparison the rate of mortality of the three first years with the rate of mortality of the three last years. The three first years give an average of 30·6 deaths for each 1,000 inhabitants, a figure which accords with the one of the previous (31·6) and of the following year 1873, which was 30·3. The three last years give as average by the years also, and upon 1,000 inhabitants, the rate of 24·9, that is to say that the rate of yearly mortality in the city of Rome has diminished by more than one-sixth from that which existed before ; or in other words, that the state of health is improved by one-sixth. Yet this is just the moment chosen by all the medical and lay papers, and by the medical profession, to raise such loud clamours about the unhealthy condition of Rome !

Such are the facts, the official facts ; but I hasten to declare that it is not by these general figures that any conclusive inference can be drawn about what is commonly reported of the fearful predominance of fevers in Rome. I cannot, at this moment, reply to these assertions with comparative tables. But allow me to add here a few considerations upon the subject, which may, perhaps, help to give a more correct idea of the actual state of things to those who wish to know the truth of what has been called *Roman Fever*. For all the Italian physicians, *Roman fevers* are the marshy fevers, *the agues* which dominate all over the *Campagna* from July to October, and attack the poor peasants who come chiefly from other provinces to work in that season. This fever disappears in winter; it does not attack at all the central quarters of Rome, and it is almost unknown amongst foreigners, who live in these quarters. But in the winter and in spring there are fevers in Rome as well as in the other great cities of Europe, to which foreign visitors are also exposed, and to which foreign physicians have given the name of *Roman fevers*, a name entirely unknown to Italians, if applied to these fevers. But upon this subject I could not say much in a letter, as the subject would require at least a large volume to be only attempted; but I will take the liberty of quoting a few points, which seem to me demonstrated by a practice of almost fifty years, of which I passed thirty-seven in Rome.

1. Typhus and typhoid fevers are less frequent in Rome amongst natives than they are in other large cities of Europe.
2. English and foreigners settled in Rome are almost never affected by such fevers.
3. Italians coming to spend the winter in Rome are very seldom affected with it.
4. Servants of the various hotels in which foreigners have been seized with such fevers are never affected with it, although in many cases they are Germans.
5. In my first 27 years' practice at Rome I scarcely met 4 or 5 cases of real dothienenteritis. Fevers had then the type of what we should call now cerebro-spinal; very few physicians thought it infectious, and no signs existed of any attack of Peyer's glands or Fuller's follicles.
6. When the French army occupied Rome in 1849, and for many years after, all the soldiers who took fever in winter and spring got it always of a dothienenterical, pythogenic, or typhoid form, if they were seized with it during the first six months of their arrival; but after eleven months not one took it but of the other form quoted above. This observation was communicated to me by Dr. Mayer, a distinguished physician who had charge of the health of the army, and with whom I had occasion to attend many fever cases.
7. During the last seventeen years fevers have taken the common pythogenic or dothienenterical form, and it is almost exclusively this form of fever with which foreign visitors are affected. It was in the first years more frequent and violent, now has grown less frequent and very mild.
8. No doubt many of these fever cases were originated at Rome, but probably many more originated by the infectious influence of other cities through which travellers passed, like Naples, where the drainage is very bad: on arriving in Rome, it developed after the known incubationary period. In my practice I have reckoned as many as thirteen out of seventeen cases which I had reason to believe originated *out of Rome*.

If you think these remarks may have any interest for your readers, or be useful to the profession, I shall be glad if you will publish them in your widely-read columns, asking you at the same time to make due allowance for a foreigner writing in the English language.

I am, &c.,

D. Pantaleoni, M.D.

102 Ripetta, Rome.

[It gives us pleasure to accord space to Dr. Pantaleoni's letter, which will doubtless be read with interest by many of our readers. We may add that our figures given weekly on the mortality of foreign cities are likewise official, being supplied to us by the Registrar-General. We would call our correspondent's attention to the figures in another column, by which he will see, that according to the last weekly return, Rome gives a death-rate of 42 per 1,000. In our issue for Dec. 31st the statistics furnished to us by the Registrar-General gave the death-rate of Rome at 41 per 1,000, this being in each case the highest of any foreign city, which is hardly compatible with Dr. Pantaleoni's views.—Ed. M. P. & C.]

## METHODS OF MEDICAL EDUCATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Some recent numbers of the *Medical Press* having by chance fallen into my hands, I read in them with great interest the articles on the "Method of Medical Education," and while heartily endorsing everything that has been said in them, I would wish, with your permission, to add a few words on the subject from the medical student's point of view.

In my humble judgment there are three things which are absolutely necessary in order to simplify the whole system of medical education. What is required in the first place is an assimilation, as much as possible, of all the different medical degrees, so as to obviate the difficulty which meets the student at the very commencement of his studies of being unable to make up his mind which is the best degree to go in for. That subject, I believe, is at present being considered by the Government, and we may therefore, I hope, soon have some effective legislation in that direction. The second point I would strongly urge, as your paper also does, is a readjustment and subdivision of the examinations, and a kind of supplemental preliminary examination which would embrace the rudiments of those branches of medical knowledge which are at present required to be thoroughly mastered before even the first half examination can be passed. I am myself in my third year, and though I have tried to be fairly industrious, I must honestly confess that I have never yet opened a book on Chemistry, Botany, or Materia Medica, and I look forward with dismay to making their acquaintance, having been so long without even a rudimentary knowledge of them. While on this point I may mention as an illustration, whether of the good or evil results of the system of "cramming"—for it may be looked on in either light—that a friend of mine who has now a good practice in a certain large city, assured me that he had never opened a medical book until the *four months* previous to his going up for his examination, and yet he passed with flying colours.

The third point I would suggest is a more compulsory method of teaching; not of course like the ordinary schools, but by a strict and inflexible system of calling the roll for lectures, and a refusal to grant the certificates of attendance to those who are absent more than a certain small percentage of times. At present there is too much tendency altogether to let the student shift for himself as best he may, and act on his own discretion. Of course you will understand that I do not want us to be treated as mere schoolboys. We are supposed to have left all that behind us when we entered the medical profession; but I think it should be impressed on us more strongly than it is at present, that the study of medicine is no child's play, and that if we do not "scorn delights and live laborious days," we should at least bring to our studies as much assiduity and industry as is employed in any other business or profession.

Another point I would strongly urge is the doing away with compulsory attendance at hospital for the first year or so until at least an elementary knowledge of anatomy and physiology is acquired. The lectures might then commence earlier in the day, and more time could thus be given in the afternoon for study, grinding, and dissections.

Should you be good enough to give me space in your journal I would gladly return to the subject at another time, and touch upon some anomalies of medical education, which, with your influence, might be eradicated, or at any rate toned down. I enclose my card, but not for publication, and am,

Yours, &c.,

Rusticus.

◆

## ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—With reference to my letter concerning St. John's Hospital, which was published in your issue of November 12th, it has been suggested to me that I ought to explain why I was not present at the meeting of Governors of the Hospital in September last, to make any complaints. To begin, it may be unnecessary for me to repeat the remark in my letter to the board, which may probably have led to a meeting of governors at a time when most of them were out of town, but I may state that in July last the Secretary sent round letters to the subscribers containing the following:—"For unavoidable reasons the annual meeting of governors has been postponed from time to time. It will now be held definitely next month (August) when the Board of Management earnestly hope,"&c., &c. During the next six weeks I kept a sharp look-out for any notice of the meeting to be held, but seeing none, I concluded, consistently with the Secretary's letter, that the idea of holding it at such an unusual season had been given up, and on Friday, the 5th September, I landed in Holland to take part in the International Medical Congress, which lasts eight days. On the following Tuesday, the 9th of September (not August) letters were written, and cards sent to governors for a meeting to be held on the following Monday, and when I returned next day (Tuesday, 16th) the first intimation I had of the meeting was that it had been held on the previous day. That the meeting should be called and held within the eleven days during which I was out of the country will strike most people unacquainted with the manner in which business is conducted at St. John's Hospital as a curious coincidence. I may also state that, although by the printed rules of the Hospital I was a governor for the year in question, I had no notice from first to last of the meeting, and no card of admission was forwarded to me.

Had I managed to obtain admission to that meeting, I should certainly have called attention to the item of £111 14s. put down in the accounts at page 13 as the amount received from patients, and I should have stated that according to estimates I have already challenged the board to disproved that figure was less than it ought to have been by at least £1,000. As in the case of a similar item mentioned in my last letter, "the serious question is, What has become of the balance?"

I should also have called attention to the number of out-patients alleged to have been treated during 1878, and asked how many patients paying five shillings a visit were put down as five patients, so as to swell the list and increase the grant from Hospital Saturday and Sunday Funds. In fact, to remove any doubt respecting the numbers of out-patients attending the Hospital, one has only to compare the numbers alleged to have been treated during the year 1877 as they appear in the last two reports. In the 14th annual report, at page 9, they are given as 23,540, while at page 7 of the 16th annual report (when was there a 15th?) they are put down for the same year as 20,074, only a paltry 3,466 out-patients to be accounted for in a year's accounts!

I might also have asked in how many annual reports the coachmaker's labourer died of cancer, and referred as well to many matters of public importance connected with this in many ways remarkable public charity; but fearing that I have already trespassed too far on your valuable space, I shall leave them with your permission for a future occasion.

I am, &c.,

George Hoggan,
Late Physician to St. John's Hospital for
Diseases of the Skin.

7 Trevor Terrace, Rutland Gate, S.W.
31st December, 1879.

◆

# Novelties.

## STRUTT'S ABSORBENT COTTON-WOOL.

Absorbent cotton-wool is far superior to the ordinary wool for application in many surgical cases, as for instance, discharges from the ear. For dentist's purposes there is no comparison between the two forms. Absorbent cotton may be readily carbolised, and then forms one of the best antiseptic applications. It is already largely employed in surgery, and as it becomes better known its popularity must increase.

◆

## RESORBENT DRAINAGE TUBES.

The attention of the profession in this country has recently been drawn by Mr. MacCormac, of St. Thomas's Hospital, to a new tube made of decalcified bone instead of india-rubber. These tubes are made from selected bones of horses and oxen; the hard earthy salts are abstracted by chemical action, until nothing remains but beautifully pliable gelatinised tubes. Thus treated they are said to cause less irritation than existing instruments, and we hear that Dr. Granville Bantock has just used them in a breast case with excellent results. The idea is due to Dr. Neuber, of Kiel, and from what we have seen and heard of them, these tubes are likely to supersede those previously in use. Another advantage claimed for them is that having served their temporary purpose, they melt away, and the dressings do not require to be changed for their removal. Dr. Neuber finds that wounds thus treated may remain without change of dressing from two to four weeks. The sole agents in this country for these tubes are Messrs. Krohne & Sesemann, 8 Duke Street, London, W.

◆

## A HYGIENIC STOVE.

The "Hygienic Stove and Grate Company" have introduced a stove that is admirably adapted for use in hospital wards, combining, as it does both advantages of an open fire and almost perfect ventilation. We have inspected the stove in action in several places, and we find it really does embody the essentials of a hygienic warming apparatus. By an ingenious arrangement a constant current of pure air is passed through a heating chamber, and thence enters the room free from noxious gases, while being at the same time undeprived of the moisture necessary for the healthy maintenance of the animal functions. In all other stoves one or other objection in present—either the heated air is dried to an injurious extent, or else it is incorporated with gases hurtful to those breathing it. The novelty has been for some time in use at the Queen's Hospital, Birmingham, giving great satisfaction; and it has been most favourably noticed at the late Croydon Exhibition. We venture to think that a wide appreciation and use of the stove will lead to the removal of much of the remediable misery connected with ward management; especially would its introduction lead to the alleviation of the distress at present experienced by delicate patients from the draughts of cold air which are admitted into wards for ventilating purposes; and its simplicity, together with the bright, cheerful appearance of the stove, render it a much to be desired improvement.

◆

## BILIN MINERAL WATER AND DIGESTIVE PASTILS.

Although introduced to this country as novelties, they will be recognised as very old friends by travellers on the Continent, especially in Austria and Germany, where the water is very widely drank both medicinally and as a table water. The source from whence the waters are bottled is at Bilin, in Bohemia, and from their alkaline characteristics, their richness in the bicarbonates, they should be principally useful in restoring the impaired mucous membranes to their normal functions, also in gouty or rheumatic complications. Possessing a considerable quantity of natural carbonic acid gas, it is not an unpleasant table water. The pastils are prepared from the waters by evaporation, and compounded as they are with sugar, form an agreeable method of taking the remedy wherever indicated. We may add that they have found their way into the Austrian Pharmacopœia, and are now introduced like so many other foreign waters into this country through the medium of a London house.

◆

## MALTED CHOCOLATE.

Extract of Malt having deservedly become such a popular remedy with the profession and the public, it is not surprising that a rivalry should exist among manufacturers for the best and most attractive form of its introduction. One of the newest, and certainly one of the most palatable, is that now before us in the shape of Extract of Malt combined with Chocolate Paste. The names of the manufacturers are so well-known for the excellence of their specialities, as to render criticism superfluous. Messrs. Allen and Hanbury are responsible for the Malt Extract, and Messrs. Fry and Sons, of Bristol, for the Chocolate Paste. Thus prepared, even teetotalers can enjoy a cup which really "cheers, but not inebriates," the extract being free from alcohol; whilst invalids and those who habitually drink cocoa will be enabled to partake of their favourite beverage, in combination with that useful restorative Malt Extract, in a most agreeable and assimilable form.

◆

## DUTCH COCOA.

The demand for non-alcoholic drinks is undoubtedly, and perhaps fortunately, assuming larger proportions, as the public begin to take an interest in, and understand the diet question. Commercial men are not slow to take advantage in these exigencies, and the demand is immediately met by supply. We have before us a cocoa which has recently been introduced to this country by Messrs. Tulloch and Sons, under the description of "Pure Dutch Cocoa." Having prepared it according to the directions given, a cup of refreshing aromatic cocoa, freed from all superfluous fat, was obtained. We are glad to notice the increasing demand for these unadulterated articles. But a few years ago, the uninstructed public imagined that unless cocoa was of about the consistence of treacle, it could not be genuine; our Reports on the cocoas of commerce altered this, and opened their eyes to the deception practiced by the addition of potatoe starch and bad arrowroot. This Dutch cocoa will doubtless take its rank side by side with the best English manufactures.

◆

## NELSON'S PURE BEEF-TEA.

Whilst yielding to none in our preference for beef-tea, made fresh and fresh from the meat, there are, nevertheless, innumerable instances where this is impossible; and here such a preparation as Nelson's prepared article becomes invaluable. It is a highly concentrated gelatinous substance, cut by machinery into very fine strips, the quantity for each cup is put up into small packets, so that the nurse has simply to empty the contents of one into a cup, pour in hot-water, and the beef-tea is ready for use. Thus prepared it has the aroma of beef-tea made by the ordinary process, and if allowed to stand till cold, a substantial and nutritive jelly will be found. On the whole, it is one of the best articles of the class we have ever examined.

◆

## NEW HEPATIC REMEDIES.

In an abstract of his experimental researches on the physiological actions of drugs on the secretion of bile, Dr Rutherford mentions a few comparatively new cholagogues which seem worthy of the attention of practitioners, and which we introduce to their notice.

Resina Hydrastis, or Hydrastin.—The root of the hydrastis Canadensis is admitted by all to be tonic, and by some it is said to be aperient, cholagogic, diuretic, antiseptic, &c. It contains an alkaloid, hydrastia or hydrastin, which has been found to be identical with berberin. The hydrastin employed by Dr. Rutherford was not the alkaloid, but a resinous substance prepared from the root of the plant by Keith and Co. The dose for a man of this preparation is from one to two grains. His experiments proved it to be a moderately-powerful stimulant of the liver and a feeble stimulant of the intestine.

Resina Juglandis, or "Juglandin," is an impure resin prepared as above from the root of the butter-nut (*juglans cinerea*). Regarding the properties of the bark of the butter-nut, Wood and Bache state that it is a mild cathartic, operating without pain or irritation, and resembling rhubarb in the property of evacuating without debilitating the alimentary canal. It was much employed during the late American Civil War by Dr. Bush and other army physicians. It is especially useful in habitual costiveness and dysentery. Nothing is stated regarding any influence on the liver. An extract of the bark is officinal in the United States. The dose of Keith's juglandin—the substance used in our experiment—is from two to five grains. In the dog it is a moderately powerful hepatic and a mild intestinal stimulant. It seems to be worthy of the practitioner's attention.

Resina Baptisiæ, or "Baptisin," is prepared as above from the root of the wild indigo (*baptisia tinctoria*). The root of this plant is said to be a powerful emetic and cathartic in large, and a mild laxative in small doses. Stevens, of Pennsylvania, recommends a decoction of the root in epidemic dysentery. It is said to have proved useful in scarlatina, typhus fever, and in that state of the system that attends mortification.

The physiological actions of this plant have apparently not been investigated, and it is nowhere stated that it is a cholagogue. The dose of baptisin for a man is from one to five grains.

Our experiments prove this substance to be in the dog a hepatic and also an intestinal stimulant of moderate power. It may possibly be found of service as a hepatic stimulant in cases of torpid liver, with a depressed condition of the system tending to gangrene. We recommend it to the attention of the physicians.

Richardson and Co., of Leicester, supply the above drugs in the form of pills.

◆

# Medical News.

**Bequests to Medical Charities.**—The London hospitals, and a few in the provinces, have just received some substantial bequests under the will of Miss Harriet Hurst, late of Stamford. These are: the London Hospital, £5,000; the Middlesex Hospital, £3,500; £3,000 each to University College Hospital, St. George's Hospital, and the Stamford, Rutland, and General Infirmary; £2,000 to the Westminster Hospital; £1,000 each to the Cancer Hospital, Brompton; Charing-Cross Hospital; St. Mary's Hospital; the General Infirmary at Hertford; the Hertfordshire Seaside Convalescent Home; the Wolverhampton and Staffordshire General Hospital; the National Hospital for the Paralysed and Epileptic; the Asylum for Idiots, Earlswood; the Hospital for Sick Children, Great Ormond Street; the Hospital for Consumption, Brompton; and the City of London Truss Society; £500 each to the Huntingdon County Hospital; St. Peter's Hospital for Stone, the Royal Medical Benevolent College; the Royal Free Hospital; the London Lock Hospital; Lincoln Hospital; Kent and Canterbury Hospital; Royal London Ophthalmic Hospital; Metropolitan Convalescent Institution, Walton-on-Thames; Hospital for Women; Evelina Hospital for Sick Children; and the Hitchin Infirmary; £300 each to the Hospital for Diseases of the Skin, Samaritan Free Hospital for Women and Children, and the National Orthopædic Hospital.

## NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Indian Medical Candidates are notified that an examination for twenty-three appointments as Surgeon in H. M. Indian Medical Service will be held in London on February 9th. The announcement will be found in our advertisement columns.

Mr. T. P. T.—The gentleman named has ceased to act in that capacity.

Hunterian Society.—This (Wednesday) evening, at 7½ o'clock, Council Meeting.—8 o'clock. Dr. Herman, "On a Class of Cases in which Relief may be given by the Use of Vaginal Pessaries."—Dr. Braxton Hicks, "On Lateral Obliquity of the Pregnant Uterus."—Dr. Galabin, "On a Case of Unusual Pelvic Deformity."

**Mr. Salmon.**—We consider the last edition of Naphey's "Therapeutics" decidedly more useful to the general practitioner than Ringer's.

**Prof. Landolt** is thanked for his appreciative note. The subjects contained therein will be referred to in our next.

## ARCTIC EXPLORATION AND ALCOHOL.

*To the Editor of the* Medical Press and Circular.

Sir,—The agitation (which I trust will shortly be crowned with success) for a new Arctic Expedition being vigorously carried on, permit me to direct the attention of your readers to the propriety of exercising the utmost caution in the selection of the men. The experience of Capt. Kennedy's and of other Arctic expeditions indicates the superior health and the greater capacity for work and for endurance of a company to whom no alcohol is served out.

Bearing in mind the comparative failure of our last expedition, and the evidence given before a committee of the House of Commons thereon, would it not be wise to select a crew composed entirely of abstainers (if a sufficient number can be obtained), and to provide for an adequate supply of good lime-juice in an available form, as well as for the purity and mellowness of the very small amount of alcoholic liquor which should be allowed only in the medicine chest?

Your obedient servant,
Norman Kerr, M.D.

47 Grove Road, Regent's Park, N.W.,
Jan. 10, 1880.

**A Provincial Practitioner.**—We are not supposed to know the composition of all quack remedies, but we believe *Mrs. Winslow's Soothing Syrup* (an American nostrum) consists of ordinary sugar syrup flavoured with an alcoholic tincture of fennel, a little essential oil of carraway seed, and a solution of sulphate of morphine. The quantity of this latter drug differs, some bottles containing but the merest trace, in others as much as a grain and a-half to the fluid ounce has been discovered as evidence of its dangerous character.

**Obstetrical Society of London.**—This evening, at 8 o'clock, Specimens: Ruptured Fallopian Tube, by Dr. Godson; New Instruments, by Dr. Heywood Smith; One-headed Twin Monster, by Dr. Hilliard.—Paper: Dr. Champneys, "On the Pain in Pelvic Cancer, and its Relief by Morphia."

**Mr. F. V.**—It was noticed in our issue of December 24.

**A Guy's Man.**—We were first to lead the way about the nursing; our contemporaries have followed suit. At present the matter is in abeyance, as we understand the medical staff intend to at once appeal to the general body of governors on the action of the lay treasurer.

**Royal Institution.**—Thursday, Jan. 15, at 3 p.m., Mr. H. H. Statham, "On Modern Architecture since the Renaissance."

**Harveian Society.**—Thursday, Jan. 15, at 8½ p.m., Dr. Goodhart, "On Anæmia as a Cause of Heart Disease."—Dr. Broadbent, "On Venesection."

**Editor of "Exchange and Mart."**—Letter, on "Traffic in Charity Votes," with our views thereon, will appear in our next.

## THE METRIC SYSTEM.

As we are frequently asked for information on the metric system, we shall publish the annexed and other tables from time to time, with the view of assisting our readers in what is rapidly becoming a difficulty, in consequence of the frequent use of the metric notation by writers, both in our own and other journals:—

### METRIC MEASURES OF LENGTH.

| | | | | | | |
|---|---|---|---|---|---|---|
| Millimetre | 0·001 | of a Metre | equals | 0·03937 | inch | |
| Centimetre | 0·01 | ,, | ,, | 0·39370 | ,, | |
| Decimetre | 0·1 | ,, | ,, | 3·93707 | ,, | |
| Metre | 1 | Metre | ,, | 39·37079 | inches | |
| Decametre | 10 | Metres | ,, | 393·70790 | ,, | |
| Hectometre | 100 | ,, | ,, | 3937·07900 | ,, | |
| Kilometre | 1000 | ,, | ,, | 39370·79000 | ,, | (1 mile) |
| 5 Kilometres | .. | ... | equals 3 miles | | | |

### METRIC MEASURES OF WEIGHT.

| | | | | | |
|---|---|---|---|---|---|
| Milligramme | 0·001 | of a gramme | equals | 0·015 | grain |

### METRIC FLUID MEASURES.

When using the metric system, fluids are preferably prescribed by weight, employing the gramme, its multiples and sub-divisions, just the same as with solids, thus avoiding the errors due to refraction, adhesion, and inaccurate measuring vessels.

For practical purposes, four grammes of water may be regarded as equivalent to a fluid drachm of that liquid. And the same may be considered true of tinctures and infusions. Syrups, on the average, are about one-third heavier than water, so that a fluid ounce of a syrup will be approximately represented by 43 grammes. Fluids may be prescribed by volume in the metric, just as in the present system, using for that purpose the cubic centimetre, that is a volume represented by a cube, all of whose sides measure one centimetre.

One cubic centimetre (C.C.) equals 16·231 minims. It is approximately regarded as one-fourth of a fluid drachm.

## VACANCIES.

Birmingham General Hospital.—Registrar and Pathologist. Salary, £130, with board and residence. Applications to the House Governor before Jan. 26.

City of Dublin Hospital.—House Surgeon. Salary, £100, with allowance. Election, Jan. 26. (See Advt.)

Hungerford Union.—Medical Officer for No. 3 District. Salary, £80, with the usual extras. Applications to the Clerk of the Union before Feb. 10.

Irvinestown Union, Irvinestown Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Medical Officer of Health. Election, Jan. 21.

Manchester Royal Infirmary.—Resident Surgical Officer. Salary, £150, with board. Applications to the Chairman of the Board by Jan. 17.

Metropolitan Asylums District.—Medical Superintendent for the Adult Asylum at Darenth. Salary, £400, with extras. (See Advt.)

New Winchester Union.—Medical Officer. Salary, £100, with the usual extras. Applications addressed to the Guardians, St. Peter Street, Winchester, before Jan. 30.

North Dublin Union.—Medical Officer to the Workhouse. Salary, £150. Applications to the Clerk of the Union before Jan. 27. (See Advt.)

Oughterard Union, Lettermore Dispensary.—Medical Officer. Salary, £100, with fees, and £12 as Medical Officer of Health, and £10 for boat hire. Election, Jan. 24.

Queen's College, Galway.—Professor of Natural Philosophy. Election, Jan. 26.

◆

## APPOINTMENTS.

**Armstrong**, J., M.B., L.R.C.S.Ed., a Physician to the Liverpool Infirmary for Children.

**Browne**, J. W., M.B., M.R.C.S.E., Medical Registrar to the Middlesex Hospital.

**Burnett**, R. W., M.D., M.R.C.P.L., a Physician for Out-patients to the Great Northern Hospital.

**Elliot**, G. S., M.R.C.P.Ed., F.R.C.S.Ed., Medical Superintendent of the Metropolitan Asylum District Asylum, Caterham.

**Gabbett**, H. S., M.B., L.R.C.S.I., Medical Registrar to the London Hospital.

**Lowe**, H. G., M.R.C.S.E., Resident Surgical Officer to the General Hospital, Birmingham.

**McLaren**, C., M.B., C.M., House Surgeon to the Bury Dispensary, Lancashire.

**Penny**, C. H., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer for the Wymondham District, and Medical Officer of Health for the Wymondham Sub-district of the Melton Mowbray Union.

**Reid**, W., M.B., C.M., Resident Medical Officer to the Jersey General Dispensary.

**Shann**, F., L.R.C.P.L., M.R.C.S.E., Third Honorary Surgeon to the York County Hospital.

**Army Medical Department.**—Deputy Surg.-Gen. J. E. Moffatt has been appointed Principal Medical Officer of the Dublin District in succession to Deputy Surg.-Gen. E. Gilborne.

◆

## Births.

**Dougan.**—On Dec. 28, at Portadown, co. Armagh, the wife of George Dougan, M.D., of a daughter.

**Walker.**—On Jan. 3, at Shrubland House, Hackney, the wife of W. Newman Walker, M.R.C.S.E., of a daughter.

◆

## Marriages.

**Colenso—Kerr.**—Jan. 7, at St. Giles's Church, Oxford, R. J. Colenso, M.A., M.B. Oxon., M.R.C.S.E., elder son of the Bishop of Natal, to Emily Anne, daughter of the late Thomas C. Kerr, of Hamilton, Canada.

**Palmer—Fawcett.**—On Jan. 8, at Holy Trinity Church, Weston-super-Mare, Francis C. Palmer, L.K.Q.C.P.I., M.R.C.S.E., of Brigg, Lincoln, to Laura Augusta, daughter of the late Benjamin Fawcett, of Torfels, Weston-super-Mare.

**Waddington—Young.**—On Jan. 8, at St. Peter's, Lincoln, Frank Waddington, M.R.C.S.E., Armley, Leeds, to Augusta, daughter of J. M. W. Young, Lincoln.

◆

## Deaths.

**Bancks.**—On Jan. 4, at Cheltenham, Thomas Bancks, M.D., F.R.C.S., late of Stourbridge, Worcestershire.

**Bookey.**—On Jan. 7, at 28 York Street, Dublin, Richard Bookey, M.B., aged 34.

**Collis.**—On Oct. 26, at Port Blair, Andaman Islands, John George Collis, M.D., aged 32.

**Colledge.**—On Jan. 6, at Cheltenham, Caroline Matilda, widow of T. Richardson Colledge, M.D., F.R.S.Edin.

**Foster.**—On Jan. 7, at Huntingdon, Michael Foster, F.R.C.S., aged 69.

**Irvine.**—On Dec. 30, at Irvinestown, co. Fermanagh, Alexander Irvine, L.R.C.S.I., aged 46.

**Leney.**—On Jan. 4, at Southampton, Alexander Wm. Henry Leney, M.B., L.R.C.S.I., eldest son of Dr. Leney, of Bray.

**Mainwaring.**—On Dec. 22, at Dudley, William Mainwaring, L.S.A.L., aged 80.

**Ponsford.**—On Dec. 30, at University College Hospital, from blood-poisoning contracted in the discharge of his duties as Physician's Assistant, L. C. Ponsford, aged 23.

**Scott.**—On Jan. 2, at Clifton House, Beeston Hill, Holbeck, Leeds, William Scott, M.R.C.S.E.

**Shirres.**—On Dec. 20, at Gateshead, David Shirres, L.R.C.P.Ed., aged 35.

**Taylor.**—On Dec. 28, at Easton, Elgin, Dr. James Taylor, formerly of the Hon. East India Company's Service, aged 76.

**Yonge.**—On Dec. 25, at Liskeard, John Francis Duke Yonge, M.D., aged 65.

## ON ALCOHOLIC VASCULAR TENSION, AND ITS EFFECTS.

By JOHN C. THOROWGOOD, M.D., F.R.C.P.,
Physician to the City of London Hospital for Diseases of the Chest, &c., &c.

Some will say, on observing this title, that it suggests the idea of an individual being what is termed "tight" from the effects of drinking too much, and this is precisely the idea on which I am desirous to enlarge, for the familiar word "tight" expresses a deeper physiological meaning than may at first sight appear.

Some months ago a young gentleman, robust in frame and of healthy aspect, came to me in much alarm on account of his having coughed up about a teaspoonful of blood. I examined his chest very carefully, and could only say that there might be a little congestion about the right lung. I saw him again in a week, and he then told me that in the interval he had seen two very distinguished physicians, one of whom had given him a written opinion that he thought there was slight congestion of the right lung, the other said he could find no sign of disease in the chest. Now, this young man had a firm quick pulse, a coated tongue, and a hot skin, and owned to habitually drinking an amount of ale and spirits that quite startled me. He evidently had a strong propensity for alcoholic liquors, and one of his physicians said plainly to him that he would rather have a tendency to consumption than have such a liking for to alcoholic beverages as had the patient. I told him he certainly got a good two guineas' worth of advice, and recommended him not to forget it.

The case seemed to me to be one of by no means an uncommon class, where a constant state of vascular tension issues in a hæmorrhage, it may be from the stomach, bowels, or lungs.

Persistent excess in the use of alcohol by a healthy person maintains a condition of extra pressure and strain on the small vessels, which at last finds relief in a hæmorrhage.

If the patient be somewhat on in years and have weak degenerative vessels, then a condition of tightness and over pressure is most dangerous. How often do we have to see a robust looking man suddenly struck down by cerebral hæmorrhage. Probably he has had a good dinner and drunk liberally, and when the doctor arrives, and finds the poor man senseless on the sofa, everyone says that he had been congratulated only the day before and told how well he was looking.

Supposing the vascular tension induced by a too free use of alcohol does not at once issue in a bleeding, it appears to maintain a constant strain on the heart and vessels which seriously impairs the nutrition of these structures, so that the weak and wasted coats of the blood vessels become very prone to laceration and rupture—a condition well expressed by the popular term "rotten from drink." Thus cirrhosis of the liver and granular disease of the kidney may be set going.

The variability in the degree of blood pressure, according as the patient is or is not under alcoholic influence, produces a singular irritability of the nervous system. Sleepless nights with palpitating heart, morning retching and coughing, and utter want of appetite for breakfast, are among a few of these effects.

Want of decision on momentous points, impatience and recklessness, tinglings, numbness, and shooting pains, are other signs of disturbed innervation.

The sudden withdrawal of all stimulus from these persons who have been living in a perpetual state of excessive tension and strain is followed by more or less collapse and sense of exhaustion and sinking, driving a few weak ones back to the drink as being their only safeguard from doing something dreadful.

The best advice to give during this very painful and trying crisis is to encourage the patient to outlive it, by assuring him that it is but temporary, and to take care that he is well supplied with the best of nourishment, and with good fresh coffee when he feels especially down and low, while at the same time he takes a bitter tonic medicine, and under this regimen, and a fair amount of resolution on his own part there comes in time a renewal of life, and a restoration of nerve that is most satisfactory to witness.

# Translations.

## OPHTHALMOLOGICAL NOTES.

Translated by ARCHIBALD HAMILTON JACOB, M.D. DUB., F.R.C.S.I.,

Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital and Dublin Eye and Ear Infirmary.

### *Contributions to the History of the Development of the Human Eye.* (a)

In the human embryo at about four weeks the crystalline was not yet separated from the *stria cornea*. Although there was at this level a depression of the ectoderm, the author does not venture to pronounce an opinion as to whether the crystalline is at first a full body, becoming at a later period an empty one, or whether it be from its first appearance empty.

The homogeneous vitreous body, without cells, was already in existence between the crystalline and the retina, although the sanguinary vessels had not yet penetrated into the interior of the ocular vesicle. It was in direct communication with the mesoderm.

The internal limiting membrane of the retina is already in existence at this early epoch of intra-uterine life.

### *The Determination of Astigmatism.* (b)

For the determination of astigmatism the author recommends the following modification of Snellen's star (*étoile de Snellen*) :—Instead of equal and equidistant rays, groups of three lines are arranged round a common centre with intervals of ten degrees ; these lines become thinner towards the centre, as in No. 12 of Snellen's ladders (*échelles de Snellen*). Their size towards the centre corresponds to No. 6 of Snellen ; therefore, if there be a difference of refraction in the meridians of the eye, on Van Haaften's figure being viewed from a distance, the groups of lines will be distinguishable in different degrees, *e.g.*, at the periphery, $V^6_{12}$ will be sufficient, whereas at the centre $V^6_6$ will be required.

Then follow statistics of 735 cases (1,273 eyes) of astigmatism, observed by Snellen since 1869, the degree and nature of the astigmatism being given. These statistics form a sequel to those already published by Snellen. (c)

### *On the Depth of the Anterior Chamber of the Eye.* (d)

The author has modified an instrument, already described by Donders ("Report of the Fourth International Ophthalmological Congress," held in London, August, 1872), for measuring the depth of the anterior chamber. According to a table of data obtained by the examination of 41 eyes, we find that the depth varied from 2.68 to 3.67 mms. (from the anterior surface of the cornea to the edges of the pupil), the mean depth being 3.19 mms. In 19 emmetropic eyes the depth was found to be 3.065 mms. ; in 13 myopic 3.266 mms. ; and in 9 hypermetropic 3.09 mms.

### *Report on the Vision of Railway Officials.* (a)

Donders has made a series of experiments, highly important, inasmuch as they clearly prove that even with the ordinary coloured signals, used on the line on which they are employed, railway officials suffering from colour-blindness frequently make mistakes which might seriously affect the railway service. Donders constantly makes use of his *quantitative method* (small pieces of coloured paper on a dark back-ground) for the discovery of chromatic anomalies, and has, on all occasions, found it eminently successful.

### *Pathological Demonstration on the Incomplete Decussation of the Optic Nerve in Man.* (b)

Nicati has proved that in the cat decussation of the optic nerve is incomplete, and Dr. Gowers has observed in man a case of lesion of the optic tract, which for precision and clearness of demonstration, is but little inferior to an experiment in the laboratory.

A man, æt. 40, who had for some months suffered from headache, came for advice ; he was suffering from left typical hemiopia, part of the field of vision of each eye being defective. During several months he was attacked by epileptic-like fits, followed by left hemiplegia, and death. On examination a small tumour was discovered in the infero-internal part of the temporal lobe, at that part where it covers the cerebral peduncle ; the tumour had traversed the optic tract, and attacked the cerebral peduncle. This optic tract was atrophied so far as the chiasma ; the left was in a normal condition, as were also both optic nerves.

### *Studies in Congenital Daltonism.* (c)

The author has examined with the greatest care, and by means of nearly all the usual processes, one hundred cases of Daltonism, which have fallen under his observation in the Schools at Breslau. He has not met with a single case in which a girl was thus affected, whereas in boys he has met with 4 per cent. A thorough examination was made in all these cases from all points of view, which could in any way be brought to bear on this anomaly : visual acuteness, colour of the hair and of the iris, refraction, hereditary transmission, consanguinity, ophthalmoscopy, &c., have all been recorded for each case in particular. The processes of Holmgren, Stilling, and Daae, the relative discs of Maxwell, perimetrical examination, letters embroidered in coloured wools, simultaneous and successive contrast, &c., have all been employed. Cohn particularises the names given by the patients to the different colours, and thus proves most emphatically that it is impossible to find even a trace of system in their answers, that is in those of patients belonging to the same category. As to the spectroscopic examination of these 100 patients, he isolates a spectral colour, and the patient is then required to point out in a collection of coloured wools all those which appear to him to be identical with the spectral colour. (d) An excellent method of verification, especially in cases in which this anomaly is simulated, consists in causing the patient to look at the wools through coloured glasses ; he is then, in most cases, able to distinguish the pseudo-iso-chromatic colours. Out of 100 cases examined, in 80 only was there blindness to green and red, and in 5 only blindness to yellow and blue (one of these consequent on detachment on the retina). These 5 cases cannot however be considered as typical, in the same degree as the 80 preceding cases; 12 cases were recorded as blind to all colours; no colour being clearly perceived. Although these 12 cases should only be qualified as completely colour-blind with great caution, still the researches of the author clearly prove that an eye deficient in red is deficient also in green, and *vice versa;* the same may be observed of yellow and blue, which are always combined. Cohn consequently pronounces in favour of Haring's theory of colour-sensation.

(a) "Rapport Aangande het Onderzock van het Gezichtwermsgen von het Personeel der Maatschappy tot Exploitatie van Staatspoorwegen." By F. G. Donders (in *Négentiende Jaarl Verslag, &c.*, in *het Nederl. Gasthnis voor Ooglijders*).

(b) Dr. Gowers, London. (*Centrabl. für d. Med. Wissensch.* 1878. No. 31.)

(c) Herman Cohn (*Studien über angeborene Farbenblindheit*). Breslau : E. Morgenstern.

(d) This modification of Holmgren's process was first recommended by Magnus. As to Cohn's rather violent vindication of his claims against Magnus, it appears to us that the difference is somewhat the same as that between the *form* and *shape* of a hat. I tis, however, difficult for us to admit that Magnus was ignorant of the fact that to patients suffering from colour-blindness, several spectral colours appear to be the same in tint, as is proved by the term "pseudo-isochromatic colours," which has now been in use during several years.

From the 100 propositions, in which the results of these researches are summed up, we cite the following:—(*a*) as a preliminary method Cohn recommends Holmgren's method, but considers it superfluous to begin with the specimen-colour green, pale rose-colour being amply sufficient in all cases of deficiency; (*b*) 6 times only there was consanguinity of parents, 3 times the father was also colour-blind, and 14 times the brother; (*c*) a few patients slip through the examination by Stilling's isochromatic sheets; (*d*) each patient was in fault with Daae's sheets; (*e*) the process of simultaneous contrast (coloured glasses) is unsatisfactory, at least, if the patient be required to name the colours; (*f*) the greater number of patients observed the greatest luminous intensity of the spectrum in [yellow, 12 only in greenish-yellow; (*g*) the few cases recorded of blindness to yellow and blue all exhibited some anomaly in the perception of red and green; (*h*) most patients in whom the eye is deficient in all colours, observed the greatest luminous intensity of the spectrum in blue or green; (*i*) no amount of practice can cure chromatic deficiency; (*j*) the spectrum in all forms of colour-blindness is generally normal in extent; (*k*) the eyes are not further apart than usual in persons affected by colour-blindness (this is contrary to the opinion of Niemetschek) Then follow descriptions of certain contrivances for detecting simulation of Daltonism.

It is much to be regretted that Cohn has not more fully described chromatopsy from a quantitative point of view, *e.g.*, by means of Donders' process. It is true, however, that according to Cohn, chromatopsy in a normal state, already varies too much from a quantitative point of view.

(*To be continued.*)

◆

# Clinical Records.

## ST. MARY'S HOSPITAL.

*Double PoplitealAneurism.—Aneurism in Right Scarpa's Triangle—Double Aortic Bruit—Ligature of left Femoral Artery—Recovery—Rupture of Femoral Artery near Seat of Ligature four weeks after Operation—Amputation—Inability to arrest Hæmorrhage—Death.*

Under the care of Mr. NORTON.

PATIENT, admitted April 1st, was married; had two healthy children; had no particular illness; never had rheumatic fever; had a sore ten years ago, followed by no sore throat, rash, or other symptoms. Father and mother alive; father healthy, mother suffers from hæmoptysis. Does not drink much in excess; four pints a day, no spirits; smokes an ounce of (Cavendish) tobacco a day. Was in the Army Service Corps seven years ago as a butcher; before that for three years in the cavalry. Three weeks ago was carrying a weight down a ladder, he slipped, hitting himself in the ham. Did not feel it much at the time; was stiff the day afterwards. Since then the swelling has come on; went on with his work to the 30th, though the pain was very severe. It was three days after the accident that he first noticed the swelling; his attention was called to it by the pain; experiences a numbness and tingling sensation in his left foot. Legs have never swelled at all. For some time past has felt a tightness across the chest, but never any actual pain. Has not lost flesh; has always been thin.

P. C. Patient is dark, somewhat sallow complexion; no fat. Skin natural. Tongue moist, fairly clear. Bowels always regular. Pulsation visible in neck and face. Pulse 84. Chest well expanded; intercostal spaces well marked. Resonance good. Entry of air good throughout. Apex beats in normal space; impulse diffused over both fronts; loud double aortic murmur heard in neck and under clavicles; heart's action regular; pulse regular, somewhat bounding; artery can be felt under the finger. A murmur can be traced round in the left axilla mitral. Area of cardiac dulness enlarged; some bulging of the left side of chest; abdomen normal; liver dulness normal. Veins of both thighs prominent. Cicatrix on penis; none in groins; femoral artery can be felt in left groin; in right groin at base of Scarpa's triangle it can be felt enlarged; it becomes much enlarged lower down; a distinct thrill can be felt, and a loud rasping double murmur audible; pulsation can be felt some way down the thigh. In left popliteal space there is a swelling of about the size of a large hen's egg, pulsating freely, expansile sideways. Pressure on femoral stops pulsation and empties it. Measurement round left knee 13¾ in. Pulsation is limited to the swelling. Veins of legs and feet very prominent and full; feet warm. Pulsation can be felt in both anterior and posterior tibials at ankle. In right popliteal space a swelling can be felt of the size of a Tangerine orange, pulsating as the other; measurement barely 13 inches. Bruit can be heard in both swellings, but in the left there can be felt a distinct thrill; not so in right. Has free movement of right leg; not so of left. Complains of numbness in left foot. From the right aneurism a double bruit cannot be heard, but it can from the one in the groin, and also in the left.

Treatment adopted—

℞ Potasss. iodid., gr. v.;
Ferri et am. cit., gr. viij;
Aq., ℥j., t. d. s.

Simple diet—Eggs, ii.; custard; porridge.

In his work has not been obliged to carry heavy weights, nor has he been obliged to use his chest. Right measurement 13 in. Veins of left leg very full and prominent; feet not cold. According to Dr. Jones' sphymographic tracing, aortic derangement (taken on left radial).

Rep. mist.
Potass iodid., gr. xx.;
Tr. digitalis, m. xv.
Chloral hyd., gr. xv.;
Aq. ℥i. H. u. s., si opus.

*Urine.*—Clear; sp. gr., 1015. No albumen.

April 3rd.—Pulse 86, regular, and of good force. Heart sounds remain the same. Is in no pain. Pulsation is increased in left aneurism, and the measurement is now 14½ in. There is a great deal of tension in it. At a consultation in afternoon it was resolved to try Esmarch's bandage, Mr. Norton thinking it a favourable case on account of the narrowness of the arterial opening. At 9.10 p.m. the bandage was applied in the usual way, flannel roller underneath, and then Esmarch. No circulation to be felt in sac after its application. Patient at first complained of a good deal of pain, but soon got reconciled to the bandage, and bore it well; had "pins and needles" very much, however. Knee soon became much congested and blue, and seemed somewhat cold. Was also applied for 20 mins. in evening.

On the 4th pulsation was as strong as before, and there was no improvement from the use of the bandage. Measurement rather more than on the previous day. In afternoon Mr. Norton decided to tie the artery. The operation was performed under chloroform. The patient being a bad subject for it, took it fairly well. The antiseptic spray and dressing were used. The vessel was tied with catgut ligature cut short. A thick piece of drainage tube was inserted, and the edges of the wound brought together with wire sutures. The whole leg was wrapped in cotton wool. Soon after the operation the patient was in great pain. M. xx. of tr. opii., aq. ℥i., were given. In evening pain was intense, so hypodermic injection of morphia, gr. ¼, was given. At 2 a.m. he was in pain, gr. xx. of chloral were given, after which he obtained a little rest. Temp. 97·6. ; pulse 81.

On the 5th he was in intense pain, and bathed in profuse perspiration, with a most anxious look. Tongue, rather white at sides, moist. Foot and toes warm. Unable to bear the leg in one position for any length of time.

4 p.m.—Much easier, and but little pain. Perspiration stopped. No discolouration of foot or toes. No pain over the incision. Bowels not open. Sole of foot (left) 96·4. ; sole of right foot, 97·4.

6th. Pulse 84 ; temp. 99. Had a very good night, only slight aching in foot. Tongue cleaner, moist. Bowels not open. Left foot not quite as warm as the other ; sensation perfect in it. Other symptoms the same. Wound dressed antiseptically ; no discharge, mostly healed by first intention. Drainage tube and stitches not removed. Right foot 96·8. ; left 96.

7th. Right foot 97·8 ; left 96·8. Temp. 98.

8th. Pulse 80 ; temp. normal. Tongue coated ; moist. Passed fair night, but had good deal of pain in abdomen. Right foot 97·6 ; left 96·6. Doing well. Bowels still confined. Examination of popliteal space. Aneurism completely obliterated, forming a solid mass ; commencing pulsation in the artery. Wound dressed antiseptically, and sutures removed. Pil. hyd. c. coloc. gr. x. statim. Enema simplex four hours after.

9th. Doing well. Right foot 97·2 ; left 95.

10th. Pulse 70 ; temp. 98. Right foot 97·4. ; left 96·4.

11th. Pulse 70 ; temp. 99. Sole of right foot 95·4 ; left 95.

12th. Had great pain last night in left leg from knee to ankle, which subsided towards morning. Right foot 95·4 ; left 95·2.

13th. Doing well. Wound dressed.

19th. Pulse 76 ; temp. 99·2. Complains of shooting pains in left leg from knee to foot. Does not look so well, face being much more anxious. Evening temp. 101·4.

30th. Complains of severe shooting pain in left knee extending into foot. Worse at night.

May 1. There is incessant pulsation in left popliteal space in the region of the aneurism. No thrill is felt, but there is some expansile throbbing, and it is difficult to say whether this is due to the aneurism, or whether due to the vessel above. There is a distinct thrill on the right side in the upper aneurism, with a double loud bruit. The right popliteal aneurism is somewhat diminished in size, but has distinct expansile pulsation. The cicatrix is red and has assumed the appearance of granulations.

2nd. 8.30 p.m.—Flow of arterial hæmorrhage came on from the wound in upper part of left thigh, the seat of ligature, profuse granulations having sprung up during last two days, which yesterday were cauterised with nitrate of silver, followed by pain. The hæmorrhage was produced by coughing—a copious gush of red blood—and the sister who happened to be at the bedside atonce stopped the flow by digital compression of femoral artery above the wound. A tourniquet was applied.

11.30 a.m.—Is lying quite still ; conscious. Says he is in not much pain ; wound aches a little. Pulsation about wound continues forcibly, but less so in popliteal space. Carotids and both temporal arteries pulsate strongly. There is considerable induration round wound ; has dosed occasionally. Sister says there was a slight show of blood previous to the fit of coughing. Had an injection of morphia last night owing to the pain, after which he slept soundly. Temp. last night, 100 ; this morning, 101.

2 p.m. Secondary hæmorrhage has occurred from wound in spite of tourniquet ; pulsation of all arteries and at wound very forcible. Mr. Norton decided to amputate just below hip ; he did so about 3 in. below the joint, making lateral flaps. The impulse from tied end of femoral was very great. Some twenty bleeding vessels having been secured, the flaps were brought together by wire sutures. Wound was washed out with a solution of carbolic acid (1 in 20), and the gauze dressings applied.

4 p.m.—Patient had recovered consciousness. Pulsation of arteries less forcible. No pain.

3rd. Vomited very much the early part of last evening. Hæmorrhage again set in, could not be controlled by tourniquet. Stump was much swollen. Mr. Norton was sent for, who immediately reopened wound and removed some very large clots, and pressed cotton wool upon the inenumerable small bleeding vessels, when hæmorrhage seemed to be fully controlled. After an hour blood effused through every dressing applied, notwithstanding compression, and the patient sank at 11.5 p.m. ;

*Heart.*—Much enlarged and uniformly dilated. There was advanced fatty degeneration on both sides of the organ. The external fat was increased. The coronary arteries were healthy, but their orifice was slightly constricted. Left with dark clot, partly decolourised. Right auricle dilated and slightly hypertrophied. Ventricle also dilated and hypertrophied ; shows marked fatty degeneration. The left auricle was immensely dilated and slightly hypertrophied ; the left ventricle was the same. The mitral valve was incompetent ; there was some nodulation near its free margin. The aortic valves were healthy, but the orifice was dilated. The arch of the aorta was dilated, especially at the great sinus ; there was great impairment of the elasticity of its walls. The inner surface was rough from fibroid thickening ; no calcification. Aneurisms of right popliteal and superficial femoral arteries.

*Liver.*—The surface was coarsely granular. There were fibroid and advanced fatty changes throughout the liver tissue. There were some pigmented spots. The pelvic glands were enlarged and deeply pigmented.

*Kidneys.*—Capsules were slightly adherent ; consistence increased. Substance traversed by white streaks due to fibroid overgrowth. Cortex narrower than normal.

*Testicles.*—Corpus Morgagni of left almost as large as a bean, of black colour. At the upper part of the epididymis is a spermatocele the size of a marble, containing opalescent fluid loaded with spermatozoa. On the right side there is another spermatocele double the size of the left.

*Amputation Stump.*—Flaps deeply separated at bases by extravasated blood. The region of the large vessels was infiltrated with exudation matter and broken-down clot. The ligature on the end of the femoral artery came away with the least traction. The lumen of the vessel was blocked with semi-coagulated recent clots, and its coats for about an inch were soft and pulpy. The common femoral and external iliacs were healthy. Th right superficial femoral was dilated for 1½ inch ; the dilatation commenced immediately below the profunda, and was fusiform in shape. The walls of the vessel were not thinned. The right popliteal artery was the seat of an aneurism half-an-inch long, by one inch wide at its greatest diameter. The dilatation is not general, only involving the posterior and external parts of the vessel. It is fusiform in shape, but somewhat abrupt at its commencement and termination. The interior presented a ragged appearance, and its wall is covered with thin, pale, laminated deposit, and over this a dirty-reddish clot. Both the apertures are patent. The wall of the aneurism is thickened.

*Microscopy.*—A transverse section through the femoral aneurism showed that the intima was enormously thickened, and roughened on the surface. The outline of the wavy elastic fibres was absent. Here and there fatty degeneration had so far proceeded that on making the section spaces with irregular lining walls were seen. On the inner surface there was laminated deposit of fibrine, which contrasted strongly (on being put in logwood) with the structure of the vessels, the former not taking the staining, while the latter did so readily. The three coats of the vessel looked infiltrated with a gelatinous materia so that their normal outlines and appearances were lost, and presented a wavy look, something like spun glass. Very few cells were to be seen anywhere. A section of the artery below the aneurism showed marked thickening of the intima, and commencing disease of the media. Sections of the aorta showed the same condition as the femoral. The cause of the hæmorrhage after amputation was the condition of the blood-vessels, which rendered them unable to contract. The changes in the blood-vessels were those which take place in syphilis, though the only evidence of the disease having existed was the cicatrix on the penis.

# Transactions of Societies.

## HARVEIAN SOCIETY OF LONDON.

Jan. 15th, 1880.

W. H. Broadbent, M.D., F.R.C.P., in the Chair.

### RUPTURED FALLOPIAN TUBE.

Mr. Rayley Owen showed a fresh preparation of this rare occurrence from a woman, æt. 49, who had recently become fat. On December 8th she was exerting herself, when she felt acute pain in the right iliac region, followed by fainting and sickness. When seen the pulse could not be felt, though the heart's action was intensified. Temp. 97. The post-mortem was made twenty hours after death, when the body was found to be still warm. All the great viscera were quite healthy, but the abdomen was full of pale blood, and in the right Fallopian tube was a perforation as large as a horse-bean. The tube itself was as large as a pipe-stem. There was no peritonitis.

Dr. Broadbent pointed out that the tubal dilatation had preceded the perforation.

Mr. Sedgewick and Mr. Alderson spoke.

### ANÆMIA AS A CAUSE OF HEART DISEASE.

Dr. Goodhart read a paper on the causal relations of anæmia to organic changes in the heart. He related four cases where such heart change followed severe and repeated hæmorrhages. He preferred to term the structural changes which followed, "tabby striation" rather than fatty degeneration, as the changes seen under the microscope were not very definite. The relations of idiopathic anæmia to heart changes had been for some time recognised. The heart's impulse is diffused, and the dilatation may go on till the mitral valve leaks. This gives what is termed curable regurgitation; but if this leakage is prolonged or repeated, the actual valvulitis may be set up. He then pointed out that mitral as well as aortic valvulitis might follow from strain in the gouty heart. There is first dilatation, then friction of the valves, and the effects of the regurgitating current, and then valvulitis. The valvular changes might lead to endocardial thickening, which in its turn may set up acute endocarditis. He recognised also the effect of high arterial tension as a cause of cardiac dilatation as well as mitral valvulitis. Mitral stenosis, he pointed out, was most common in women. The practical point of all this, he showed, is that anæmia in women and children is not regarded sufficiently seriously, and is therefore not dealt with efficiently.

Dr. Pearson Irvine said he agreed with almost every word, and that acute hæmorrhage leads to acute dilatation of the heart. In chronic anæmia the main symptoms are often those of cardiac dilatation. He thought the addition of digitalis and belladonna to chalybeates often to be of much service.

Dr. James Pollock said he had long held the doctrines put forward that anæmia led to cardiac dilatation, and then to mitral insufficiency. The rheumatic diathesis he thought often exercised a malign influence.

Dr. Milner Fothergill spoke of the effects of anæmia upon the muscular walls of the heart, and of the mitral valvulitis found in the advanced stages of the gouty heart; equally with aortic valvulitis, the effect of strain from a high arterial tension and hypertrophied ventricle.

Dr. Broadbent spoke of the necessity of combining complete rest with digitalis and chalybeates in the treatment of anæmia. Hæmorrhage was often followed by rapid dilatation of the heart.

Mr. Alderson asked as to the utility of arsenic in such cases.

Dr. Goodhart replied that iron should be given in very large doses combined with other tonics.

The meeting then adjourned.

## SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

December 4th, 1879.

The President, A. Jackson, F.R.C.S., in the chair.

### ADDISON'S DISEASE OF THE SUPRA-RENAL CAPSULES.

Dr. Bartolemi exhibited the morbid specimens (kidneys and supra-renal capsules) taken from a case of this nature, and related brief notes of the case. The patient, a woman, æt. 39, was admitted into the Sheffield General Infirmary, May, 1879, under Dr. Bartolemi's care. She had previously been under Dr. Martin's care in the month of February for an attack of rheumatism and pericarditis. She presented the usual train of symptoms, as described in the text-books. The bronzing was most marked and uniform; more noticeable, however, where the texture of the skin was finest, and the moisture greatest, such as in the various flexures of the body. This fact Dr. Bartolemi noticed as a departure from what is usually stated in the text-book description of the disease, where the greatest amount of bronzing is described as being found in the extensor surfaces of the body. She continued under observation until 16th of November, when she died. The progress of the case was one of steadily increasing debility. After death, deposits of tuberculous matter were found in the apices of both lungs. The right supra-renal capsule was infiltrated with cheesy matter, easily breaking down, and purulent in parts. The left was granular, and presented scattered yellow, tuberculous-looking nodules; at one spot there was marked pigmentation.

A discussion ensued, in which Drs. Banham, Law, and Thomas took part, and Dr. Bartolemi replied.

### RENAL CALCULUS.

Mr. Claremont exhibited a specimen of renal calculus taken from a man aged 56, who died from the effects of nervous and pulmonary disease. He had been admitted to the Sheffield Public Dispensary and Hospital under Dr. Dyson's care in the spring of 1878, with all the symptoms of an apoplectic attack, and in a state of unconsciousness. From the immediate effects of that attack he made a fair recovery, but succumbed to an attack of broncho-pneumonia, July, 1879. The stone, an immensely large one, weighing 173 grains, was discovered at the post-mortem. During life there had never been any symptoms indicating its presence. At the post-mortem two abscesses were discovered, one in the right lung, the other in the portal fissure.

### CASE OF PUNCTURED HEART.

Mr. Goyder, on behalf of Mr. A. Jackson, exhibited the heart of a man who had received a punctured wound of the heart, said to have been inflicted accidentally by his falling against the point of the blade of a pocket knife, with which he was cutting tobacco, his hand being some way or another caught between the wall near which he was sitting and his body. The point of the blade was somewhat rounded, and not very sharp, and the force with which the wound was inflicted was described at the inquest as very slight. In fact one would scarcely expect penetration with such an instrument except violence was used. The wound was about one-third of an inch in breadth, and penetrated the left ventricle close to the septum ventricle. The external wound was made between the third and fourth ribs. The man lived half-an-hour after receiving the injury; walked a distance of about 100 yards, and died a few minutes after admission to the Sheffield General Infirmary.

Dr. Bartolemi briefly noticed the experience of a friend of his, a Dr. Trail, who told him of the case of an officer who was shot through the heart during the Peninsular War whilst advancing to attack a cottage, in which were stationed some French soldiers, and who continued his advance after receiving his wound, dying just as he laid his hand upon the latch of the door.

### REMARKS UPON THE ETIOLOGY OF GOUT AND RHEUMATISM.

Dr. Thomas read a long and interesting paper under the above heading, in which he passed in review the various views held and impressed by various authorities upon this subject from the days of Sydenham, Cullen, and the older writers, down to the present day, and touched at length upon the condition of the blood and urine in the two diseases, and upon the pathological appearances found after death. He emphasised the fact that urate of soda was never deposited in the joints of persons suffering from rheumatism, while it is so found in cases of gout. Regarding the retention of uric acid in the blood as the cause of gout, he believes this excess to be owing to want of action on the part of the kidneys, pointing out the fact that whereas in health as many as nine to ten grains are excreted in the twenty-four hours, only about four grains are passed where an attack of this disease is established. He also drew attention to the fact of the greater liability to this disease on the part of wine over spirit drinkers. He concluded his paper with a brief allusion to the various methods of treatment adopted.

Drs. Banham, Martin, Garrod, Law, Claremont, and Keeling took part in the discussion that ensued.

Dr. Banham expressed his belief that chronic rheumatic urethritis is not a distinct disease in itself. He thinks that the connection between it and the rheumatic dyscrasia is too close to permit of such a distinction being made.

Dr. Law does not believe that lactic acid is the exciting cause of rheumatism, and adduced in support of his opinion the success he has met with in treating such cases with lactic acid.

Dr. Keeling laid great stress upon indigestion, worry, and cold as being the three great exciting causes of both gout and rheumatism.

## EPIDEMIOLOGICAL SOCIETY.

President—Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S.

A meeting of this Society was held at University College, Gower Street, on Wednesday, January 7th, when two papers were read, the first by Dr. Norman Chevers, entitled

### NOTES ON THE RELAPSING FEVER OF INDIA,

of which the following is an abstract.

Relapsing fever, having been recognised in Europe in 1842, was first distinctly observed and described in India by Dr. Robert Lyall in 1852-53. Our knowledge of the disease, however, enables us to perceive that very extensive and destructive epidemics of Indian relapsing fever occurred in the North-Western provinces in 1816 and 1836. In giving histories of these epidemics the author remarked that it is particularly noteworthy that the first visitation of Pali plague prevailed in Western India from 1815 to 1819, and that the outbreak of relapsing fever in 1816 described, by Mr. Jameson, occurred in the Upper Provinces only a few months previous to the commencement in Lower Bengal of the great cholera epidemic of 1817. So also, when in 1836, the Pali plague, commencing in Marwar, spread rapidly and attacked thirty-two villages of Megwar, a destructive epidemic, which must have been relapsing fever, made its first appearance in the town of Bareilly, and committed serious ravages in Mynpaorie and in the districts round Delhi. The history of the outbreak of relapsing fever in 1852-53 in the Yusufzie Valley, situated about forty miles from Peshawur, was then given from Dr. Lyall's narrative. In this epidemic were displayed all the most distinctive characteristics of the relapsing fever in India, which, unlike the cognate disease of Europe, is very destructive of life—an extremely prevalent and fatal epidemic or endemic fever arising among the poor and starved, and spreading to the well-to-do inhabitants by force of its contagiousness. The tendency to relapse is very marked; convalescence is tardy; there is generally jaundice, and quinine has no specific power as an antidote to the fever poison. Dr. Joseph Ewart, who was the first person who recognised the existence of true enteric fever in India, in 1855, noticed what he considered to be some cases of relapsing fever in Upper India at about the same time. Several years, however, had still to elapse before the occurrence of relapsing fever in the jails of Upper India was generally suspected. A very destructive contagious fever appeared in the Central Jail, at Agra, in 1860, and was described by Dr. Walker. It again prevailed in a very deadly form in the Agra Jail in 1864, and in that and the following year it appeared in the jails of Umballah, Futtehghur, Allyghur, Jeypore, Malwa, &c. It was described by the several reporters as true typhus, contagious fever, typhoid fever, and, in the words of the Sanitary Report, "some again believe it to be identical with the relapsing fever of Europe." Dr. Gray, Dr. Beatson, and Dr. Dallas clearly recognised this disease as it occurred at Agra, Lahore, and Umballah, as relapsing fever. The whole question was most fully and ably reviewed by Dr. David Boyer Smith in the *Indian Medical Gazette* for 1867 and 1868, and although his verdict met with a good deal of opposition (especially from the medical side of the Indian Sanitary Commission), he brought forward very strong arguments in favour of the opinion that the contagious fever of the up-country jails was nearly identical with the relapsing fever of Ireland, Scotland, Germany, and America. Indeed, the Sanitary Commission went so far as to admit that the disease resembles the famine fever of Europe in many important particulars. The history of the outbreak of relaping fever which commenced in Bombay, in April, 1877, was then given from the reports of Drs. Hunter, and H. Vandyke Carter, and many facts were brought forward in support of the argument that, although relapsing fever has not appeared in Lower Bengal of late years, that country was subject to the ravages up to and beyond the end of the last century.

In the second paper,

### REMARKS ON EPIDEMIC DISEASES—MEN AND ANIMALS—IN THE COLONY OF NATAL,

Surgeon-General Ross, C.I.E., after describing the geographical position of the colony of Natal, pointed out that the inhabitants of the colony at the close of 1878 are believed to have numbered 22,654 whites and 302,858 natives, 12,000 being natives of India. The area in square miles is stated to be 21,150, giving 1·07 whites and 14·7 blacks to the square mile. With so recent a history of colonisation (between twenty and thirty years), and with such a sparse population, no occurrence of epidemics would be anticipated. The climate of the colony has proved exceedingly healthy for men, women, and children; it is therefore an anomaly that, with such a healthy climate for whites and blacks, the country should be so unhealthy, and so subject to disease and epidemics, among animals. Cholera has never been known; small-pox only once caused a few cases on the Zulu border of the colony. During 1878 there was a small outbreak of typhoid among the residents of Durban, due to defective conservancy arrangements and imperfect water supply, and a few scattered cases occurred during the first half of 1879. Typhoid fever was the principal, if not the only, disease which affected the troops during the recent campaign in Zululand. The disease which affected the troops shut up in Ekowe the Medical Department classifies as typho-malarial, being a fever of malarial type, with rose spots, and well-marked lesions of Peyer's glands. There are probably two forms of typhoid fever, the one, which might be called European, arising solely from sewage contamination; the other, or more Eastern type, prevalent, perhaps, in certain latitudes, where there is the same type of fever, more due to climatic than to filth causes. Horses and mules are affected by horse-sickness, which is described as "anthrax fever," resulting from the action of a poisonous agent ingested in the food, impairing vitality and inducing a morbid state of the system, with congestive inflammation of the lungs, and often external tumours. It is believed to be identical with the Loodianah disease of India, and to be due to some poison in the grass of certain lands, probably parasitic fungi. Horses are also liable to a form of diarrhœa popularly known as "squitters." The diseases of oxen are lung sickness, red water, and quarter evil. The first of these is identical with pleuro-pneumonia; it occurs all over the colony, and is worse in some parts than others, and is not affected by climate. Red water, or hæmo-albuminuria, is a blood affection attended with more or less derangement of kidney, liver, and stomach. It lasts for five or six days, and is most fatal and prevalent after the rains of early summer. It is supposed to be due (1) to feeding on grass containing an excess of water, (2) to feeding on grass containing parasites or fungi, (3) to bad drinking water. Quarter evil is a species of malignant anthrax affecting the legs and trunk. Sheep suffer from heart water, a disease in which there is fever and effusion into the serous cavities, and said to be caused by bad pasture, dry rearing, &c. More recently, internal parasites have been discovered. Scab formerly caused great destruction of flocks, but stringent measures were adopted by law with very good results. Poultry, of which the Kaffirs are great breeders, are liable to a disease known as fowl-sickness, which sometimes empties a poultry-yard in forty-eight hours.

In the discussion which followed the reading of the two papers Sir Joseph Fayrer, Surgeon-General Ewart, Inspector-General Lawson, Dr. Buchanan, Dr. Greenfield, Mr. Netten Radcliffe, and Dr. Thorne took part.

## SOCIETY OF PUBLIC ANALYSTS.

At the annual meeting of this Society, held at Burlington House, on Wednesday, 14th January, Dr. Muter was re-elected President for the current year, and in the course of his customary annual address the President, after noticing the satisfactory position of the Society, both as to the number of members and its financial condition, pointed out that owing to it being limited to a certain class the Society was not, and never could be, a large one; but still they had a distinct *raison d'être* which they carried out, and it was something to boast of that they did act up to their aspirations, which was more than could be said of certain other associations in connection with the profession, whose limited liability had apparently extended into limited usefulness. Their Society did not pretend to elevate the morals of its members, and then find itself helpless when cases arose requiring such elevation!; neither did they pretend to raise the fees for work done, and then find that they had upon the Council some most notorious offenders in that respect; neither did they get up discussions on subjects specially the province of other societies, and end them in smoke; but what they did profess they carried out, viz., to improve the processes of analysis in all matters relating to food. Germany had always been looked upon as the foster-mother of general chemical discoveries, but Great Britain was the source of special food research, and all which had been done had been mainly attained by the members of that Society. During last year no less than forty-one memoirs relating to food analysis had been read there or published in the *Analyst*, and that was carried on not by wealthy *dilettanti* and men receiving grants from research funds, but by persons daily engaged in carrying out the complex duties thrown upon them by an Act of Parliament.

# Department of Lunacy.

## THE LUNACY INQUIRY COMMISSION.—II.

The Commissioners then proceed to give the details of a case of neglect that has come under their notice. An English tourist, travelling through a county in Ireland which is not named in the Report, was attracted by "a most peculiar howling noise" issuing from a small farm-house. Proceeding to investigate the origin of this sound, he says—

"To my horror, when I came near the house, I saw a lunatic, *stark naked*, confined to a room, and looking through the wooden bars that closed the windows, for there was no glass whatever. He is about nineteen years of age, and I have heard from his mother that up to ten or eleven years he was a most intelligent boy, but at that age he suddenly lost his power of speech, and became moody and abstracted, wandering about the fields alone, and constantly uttering a low, muttering noise, and with incessant tendency to mischief. By careful watching the family prevented him injuring himself or others, until of late he has got so strong and unmanageable, and his inclination for destruction is so great, that they have been obliged to confine him in the room I have described. He breaks the window directly it is glazed, tears his bedclothes into shreds, and won't allow a stitch of clothing to remain on his body; besides, his habits are most disgusting. It is really a sad case, and the more so as there are two grown-up sisters in the house."

The tourist having written to the inspectors of lunatic asylums, they communicated with the incumbent of the parish. He, however, had little more to add. He remarks —"The case is, indeed, only suited for a lunatic asylum. The form which his lunacy has assumed is most shocking, and is detrimental to morality."

The Commissioners do not pause to waste any indignation over this case. They merely commend the fortunate accident that led to the unhappy creature's removal to the district lunatic asylum, and they appear to think such cases by no means rare. Lest, however, anyone should say that the existing state of affairs should not be judged by one, perhaps exceptional, case, they tell us of their own personal experience.

"We took occasion ourselves to visit several of these cases in different parts of the country. Some of them we found in a deplorably neglected condition; others disturbing the arrangements of a whole family. . . . . . It admits of no doubt that many a case, if taken in hand at an early stage, might have been restored to society instead of lapsing into hopeless, incurable insanity. Serious evils often result from the freedom with which idiots of both sexes are permitted to wander abroad, often teased and goaded to frenzy by thoughtless children, often the victims of ill-treatment, or the perpetrators of offences far worse."

It is scarcely necessary to point out the studied moderation of this statement. Every sentence of it indeed might be the text of a weighty and passionate discourse. "Some of them we found in a deplorably neglected condition." There are no details here, like those which horrify one in the case brought to light by the tourist, but we may be sure that "deplorably neglected," in the careful and moderate language of the Commissioners, is a literal statement of fact. "Others disturbing the arrangements of a whole family." Now, if we consider that according to the proportion of neglected lunatics to lunatics at large, as ascertained by the Commission of 1857, there must be at present almost 4,000 neglected lunatics in this island, we shall be able to see how many families must be hopelessly disorganised by the presence of a neglected lunatic in their midst, how great must be the mass of preventible misery which this state of things brings about. Again, the reference to the torture inflicted by children (and, it might be said, ill-disposed grown persons, too) on wandering idiots is merely a hint which no one would care to have amplified whose feelings have been harrowed by having witnessed the matter referred to. Finally, much might have been said as to evils resulting from idiots of both sexes being allowed to wander unprotected through the country—often a source of hideous immorality. Not unfrequently idiot females are known or suspected to be the subjects of rape, and the number of cases of this kind that come under the notice of the police is probably small compared with the total.

Very sad and very true, also, is the remark that many curable cases are by this miserable system of neglect allowed to fall into a condition of chronic and hopeless insanity. Anyone who is practically acquainted with Irish asylums knows how many cases are constantly admitted to each of these institutions, having lapsed into a state beyond the reach of medical art—cases that might have been curable had treatment been applied in the earlier stages of their disorder.

From many causes, often from a kindly, but injudicious, reluctance on the part of friends, and often because friends fear the reproaches of their neighbours, persons are kept at home during the early and curable times of the illness, and only sent to asylums when recovery is evidently hopeless, and when relatives are weary of taking care of them. Nor should it be overlooked that this is not merely a matter of regret to the profession. It interests the ratepayer too. The incurable lunatic becomes not only a misery to himself and a sorrow to his family, but also a life-long burden to the State.

To the class of the insane who are curable but neglected, the inspection of lunatics at large, as recommended by the Commissioners, would bring relief; but something further is required in the case of idiots, to whom may be added those classed in the Constabulary Returns as epileptic imbeciles, and numbering 1,243. That an ordinary lunatic asylum is not a fit place for the treatment of idiots will be generally admitted, and even if it were, how is room to be found for such cases in the already overcrowded wards of our asylums? The idiots that are at present scattered up and down in different asylums occupy space that can badly be spared from the use of curable cases, while they are themselves too few, except perhaps at the Richmond Asylum, to justify the formation of a separate department for their care.

"There are no institutions connected with lunacy administration in England that deserve higher commendation than those that are specially devoted to the care and treatment of idiots. In no respect is the lunacy administration in Ireland so defective." What, then, can be done to improve this unfortunate state of affairs?

A large number of the workhouses in Ireland, as is generally known, were built at a period when there was much more pauperism than at present. Consequently in these buildings there is much vacant space, whole blocks or divisions being empty or only partly occupied. The Commissioners recommend that portions of several workhouses in suitable localities be so altered and arranged as to meet the want of a certain class of the insane—idiots, namely, and imbeciles. By this plan accommodation would be afforded for a considerable proportion of those who are now "neglected lunatics," while all the idiots and imbeciles from the asylums would be provided for, thereby affording a very much-needed relief to the latter institutions. Considering the requirements of the case and the circumstances of the country, and having regard to the facts adduced in the Report, and the mass of evidence which has been collected on the subject, this recommendation appears to be admirable.

The Commissioners having very carefully investigated the question of workhouse accommodation throughout Ireland, inform the Government that if this measures were carried out, "nearly 5,000 additional lunatics could be provided for." About £15 per bed is the estimated cost. In one part of the Report we are informed that "the cost of adapting the portion of workhouses that might be selected (in Ulster) would not exceed £15 per bed;" but in another page we are told "the cost of adapting workhouses as auxiliaries should not be estimated at less than £15 per bed." The estimate seems to have been deliberately arrived at and it is evident there is no desire to understate the cost of the proposed alterations. On the contrary, the tendency of the evidence seems to show that the changes could be effected for a much less sum, On comparing Ev. 2,202 and 2,203 with Appendix C. No. 8, it appears that an arrangement, once on foot, but subsequently abandoned (owing to some disputes between Poor-law and Asylum boards) would have transferred 120 lunatics from Belfast Asylum to Ballymena Workhouse. The architect employed to draw up the estimates calculated that £452 would be required to make the proposed alterations. Again, comparing the table of auxiliaries (*i.e.*, adapted portions of workhouses), given at page 83 with the Report of Mr. Wilkinson, Architect to the Board of Control of Lunatic Asylums (Appendix C., No. 10) we find two workhouses mentioned in both. The Commissioners give 75 as the approximate accommodation in the Lisburn Union, 100 in the Monaghan. Mr. Wilkinson estimates the cost of adapting the former as £768, the latter as £1,045, in each case a little over £10 per bed. On the other hand, the buildings at Castletown Devlin Union, with a cubic capacity less by 12,000 feet than those at Lisburn, would cost £1,092.

Nevertheless, with all respect to the authorities that are against us, when we consider the special wants of the insane, no matter of what mental class, and see how ill-fitted in many ways the workhouses at present are for their reception, we are inclined to apprehend that the general estimate of £15 per bed is too low. Supposing that our view in this matter is correct—let us take a wide margin, and say the cost of the proposed alterations would not average more than £30 per bed—it is still very far from being as great as that involved in the construction of new asylums. For according to this calculation 5,000 additional lunatics could be provided for at a cost of £150,000 (or if the Commissioners' estimate be accepted, at a cost of only £75,000). Turning to a previous page of the Report, one finds that the asylum at Downpatrick, built in the year 1869, to accommodate 300 patients, cost over £60,000, while the six asylums of Ennis, Letterkenny, Downpatrick, Castlebar, Monaghan, and Enniscorthy, with a total of 1,769 beds, cost considerably over a quarter of a miilion of money (more exactly £292,155 1s.) A somewhat smaller sum (£261,995 10s. 3d.) was required for six asylums built some years earlier, those, namely, of Cork, Kilkenny, Killarney, Mullingar, Omagh, and Sligo, accommodating collectively 1,760 patients. Of these Cork cost more than £79,000, and contained 500 beds.

Therefore if the question were merely one of first cost, it is, we take it, abundantly proven that the plan of adapting workhouses is vastly preferable to the erection of new asylums, since by the former arrangement (if we accept the estimate of the Commissioners) 5,000 of the insane can be housed for £75,000, a lesser sum than would be required to build an asylum for 500 patients similar to one of our present district asylums! While if we double the cost calculated by the Commissioners, and rate the alterations at the comparatively large figure, £150,000, we still reach little more than half the sum spent in the year 1869 in providing accommodation for less than 1,800 lunatics.

But there is another matter, compared to which the question of initial expense, important as it is, sinks insignificance. It is well known that the current expenses of a lunatic asylum are very large, owing to the numerous staff required, the special attention so many of the patients need, &c., and it seems to be admitted on all sides that a very considerable proportion of the insane could be supported in workhouse auxiliaries at about half the cost usual in our lunatic asylums. "In his evidence before the Select Committee on Grand Jury Presentments (Ireland), Dr. Nugent says:—'There are many poor-houses unoccupied. When they are in a wholesome, healthy situation, and where there is a quantity of ground attached to them, I can see no difficulty whatever in adding to them a certain number of rooms, and putting one or two attendants to every 40 or 50 patients, and to the patients having a better dietary than is afforded to the ordinary paupers of the institution. They could be maintained perhaps in that way at £10 or £11 per head, whereas in the ordinary lunatic asylums they would cost double that amount, totally irrespective of the cost of building accommodation for them.'"

Dr. MacCabe, Local Government Inspector, is able to give more exact information on this subject. He tells the Commissioners that there are 150 lunatic patients in Cork Workhouse, and that their total cost per head has been 4s 10d. per week. Now this amounts to £12 11s. 4d. per annum, while the average in the district asylums for the year 1877 was £24 13s. 9d. per head (compare Dr. MacCabe's evidence, p. 79, with the table given at p. 65 of the Commissioners' Report). These facts are the more important because Cork Workhouse was decidedly not one of those where the lunatics have been neglected. Of the female lunatics no less than 32 per cent. were discharged recovered during the year 1877. Though we may regret that it should have been necessary to send curable lunatics to a workhouse, though we hold that a workhouse is no fit place for such cases, yet we cannot but say that this result is most creditable, and indicates that however economical the workhouse authorities have been, they have not sacrificed the interests of the patients.

It must be remembered that the additional accommodation so imperatively required can only be obtained by adopting either of these two courses—constructing new asylums, or adapting buildings already in existence. No third proposal has ever been made, nor is it easy to see what form any such proposal could take. It remains to be seen how far the latter plan corresponds with the present working arrangements of the Lunacy Department in Ireland; how far it tallies with the recommendations of the Commissioners for remedying certain other abuses that have long been crying for rectification in that department; and how far it is supported by the evidence of the specialists whom the Commissioners have examined on the question.

### FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, Jan. 13.

M. Duplay, one of the surgeons attached to the Hôpital Lariboisiere, performed colotomy last week on a man suffering from cancerous disease of the intestines. The operator selected the right side for making his incisions, and a point usually chosen for cutting down on the external iliac artery. After detaching the peritoneum, he sought for the cæcum, which he incised, and attached the lips of the incision to the external wound. The patient succumbed forty-eight hours after the operation, and the autopsy revealed an epithelioma of the large intestine at a point corresponding to the union of the ascending and transverse portions. The symptoms during life were those generally perceived in occlusion of the gut.

Ligature of the middle meningeal artery appears to be a rash operation, impracticable in its execution, and unfaithful in its results. However, it has at least been practised three times with perfect success, of which the last was reported by Professor Huëter as being performed by him on a young lad who had the left parietal bone fractured from a fall. Called to the case, Professor Huëter, on examination, found a large open wound, from which blood flowed freely, extending from the parietal eminence forwards to the coronary suture. In exploring the wound with his finger, he felt the presence of a number of splinters that had detached themselves from the parietal. The boy was insensible. After having recognised that a considerable fragment of bone, entirely detached, was pressing on the brain Huëter hastened to extract it. Continuing the exploration, a large open fissure was discovered extending to the temporal fossa, which region was invaded by a large amount of extravasated blood. Suspecting that this hæmorrhage proceeded from a wound in the meningeal artery, Huëter decided on tying the artery by enlarging the wound. The operation was not very easy, as he had to detach from each side of the fissure several fragments with the forceps to expose the dura mater. Immediately that the artery was tied all hæmorrhage ceased. The wound was afterwards dressed according to the antiseptic method. For the three following days the patient remained insensible, but on the fourth he came to himself a little, and was able to drink. Every day afterwards saw an improvement in the symptoms, and, at the time Professor Huëter reported the case (December 1879), the cure was complete.

At the Surgical Society, M. Beauregard reported the case of a young man on whom he operated for genu valgum according to the English method (subcutaneous osteotomy). The operation over, M. Beauregard fixed the limb. The fourth day after the operation the patient could get up and walk, and on the following day he left the hospital. M. Terrillon, remarking on the case, said, that although the rapidity of the cure in this instance rendered the case interesting, he was not in favour of osteotomy; he preferred osteoclasy, that is, sudden and forcible straightening of the limb, as recommended by Delore. Osteotomy, which took its origin in England, he considered positively dangerous, as it was often followed by serious accidents, arthritis, white swellings, &c. whereas the method of Delore, which was generally adopted in France, never gave rise to such accidents.

## CORONERS AND MEDICAL MEN.

THE importance of the relations which medical men hold towards coroners is sufficiently great to justify a much more decided show of interest on the part of the profession than was exhibited at the meetings convened to consider the question. Of these, two have been held; one on December 22nd, and a second, or adjourned meeting, on Tuesday last, January 13. The business concluded at these meetings, though of a purely tentative nature, may yet, if followed up by a sufficiently vigorous action on the part of a self-constituted committee, result in the amelioration or removal of many of the objectionable practices by which the discharge of functions connected with the registration, &c., of deaths is at the present time disfigured. In Ireland is it especially felt that the position occupied by the medical witness in the coroner's court, and the unsatisfactory provisions of the law regulating his action call loudly for radical amendment. And in England, almost equally, the need and the desire for reform, and an equitable readjustment of liabilities and responsibilities are an urgent necessity.

The grave nature of the evidence given in connection with the post-mortem examination of the subjects of the coroners' inquiries has long been felt to call for the most careful attention, and to demand that the duties of such an investigation should be discharged so as to guarantee the most accurate results, in the interest of justice. Another important bearing of the same question is that relating to the enrolment of the gentlemen who undertake the office of medical witness; and it is notorious that the provisions to this end are lamentably insufficient. We cannot, however, cordially endorse the opinion of the meeting held at St. Pancras, that the necessities of the case will be met by the appointment of a specialist in post-mortem work, to conduct the examination of the bodies, and who shall receive a fixed fee of one guinea for each examination. The idea of securing a competent witness in every case is certainly commendable, but we doubt the propriety of the mode of remuneration suggested. Were this amended to a proposal to elect in every district controlled by a coroner, a fitly qualified medical referee, whose whole time and efforts should be directed to the duties of his office, more considerable benefit would be likely to accrue. The question of expense will be a consideration, naturally, but this need be no greater under the plan we propose than when that originally suggested is followed. In those places where the occasion for inquests is only rarely seen, by the union of two or more districts, under the care of a single referee, there would be obtained a sufficient area for the complete occupation of his whole time, and the distribution of the amount paid to him as salary would fall lightly on the combined centres. Thus would there be created a class of medical specialists, whose attention, freed from the worries of practice, would be wholly given to the actual work to which they were called, and out of which would arise such opportunities for pathological investigations as we may feel sure would be largely made use of, to the manifest advantage of research and advance in medical science.

The most important discussion at these meetings of medical men took place at the later sitting, on the subject of the registration of deaths. The power at present held by the registrar, it was urged, is altogether an anomaly. In order to receive from him authority for the burial of a dead person, it is requisite only that a relation or friend of the deceased shall declare the death to have occurred in his presence, and as being due to any specific disease, when the registrar is empowered to grant the document at once. As Dr. Danford Thomas pointed out to the meeting, the possible consequences of the existing law on this point may be a disastrous miscarriage of justice; for under it a murderer can appear before the registrar and *demand* an order for the burial of the victim whose death alone he is required to certify, to obtain the certificate. What it is sought to secure is, that no registrar shall have the power to give an order for burial on his own responsibility alone, but only after he has received a *medical* certificate from a duly registered practitioner, of the cause of death of the person about to be buried. The reasonableness of this is so patent, that it will commend itself to all; and some surprise may not impossibly be felt that the law permits the loose and vicious registration which is sought to be amended. In demonstration of the extent to which uncertificated deaths are registered in this country, it was averred that deaths among the "peculiar people" are registered invariably on the affirmation of friends alone; and even in the metropolitan district, Dr. Hardwicke said, 52 deaths in every 10,000 were registered in the absence of a medical certificate. In the northern and eastern counties, however, a very much higher proportion than this exists; and in the face of such truths it becomes imperative that an alteration to prevent so mischievous a condition of things shall be introduced. In pursuance of this opinion, a resolution was passed at the meeting on January 13th, to the effect that "no registrar of deaths shall be entitled to give an order for burial of a body without first receiving a certificate from a duly registered medical practitioner, stating the death to be from natural causes; or a certificate from the coroner of the district following an inquest."

The reasonable nature of such a requirement is, as we have said, apparent, and needs no enforcing. There may be less willingness, however, to respond to the call which is contained in the second resolution adopted, providing that "in no case is it desirable to refer the friends to the registrar when the medical man called in cannot satisfactorily certify to the cause of death; but that the said medical man communicate direct with the coroner's officer on a form to be supplied for that purpose, so that the coroner can judge as to the necessity for holding an inquiry. All such communications to be held strictly private." The need for some such rule as this will be found in all those cases of sudden, or more or less unexpected death, which have been preceded by no regular medical attendance, and to the cause of which the hastily summoned practitioner feels himself at a loss to certify. In every such case at present a coroner's inquiry is absolutely required; but very many of them are of a nature to do away with all necessity for this process; and the due observance of the details suggested in the resolution would in a majority of instances obviate the need of it. It would still, however, be effectual in removing the responsibility of action from the unqualified dispenser of burial orders; first and foremost, this step is paramount ere any adequate improvement can be made in the things that be. Whether or not the influence of the meeting presided over by Dr. Hardwicke is likely to effect any beneficial alteration in the law as it now stands, remains to be seen. Certain it is that the position occupied by medical men in these respects is discreditable to the dignity of the profession, and particularly is it a disgrace that the weighty power conferred on a mere official under the Registration Act should be superior to the dictum of the only opinion competent to decide the questions the registrar legally assumes to settle.

Class prejudices occupy a considerable place in the legislation that will, or should be, the outcome of the recent deliberations. As the law is at present it very often happens that a regular inquiry is very often burked because of the influence and indisposition of the friends of a deceased to undergo the discomforts and worry of such a proceeding. With an absolute and rigidly defined course of action laid down for all and every case, the possibility of anything of the kind will in future be prevented. Bu on the other hand the vexatious and needless intermeddling of the outside world will be equally deprived of the semi-official scrutiny that has in the past been to blame very frequently for the infliction of pain and annoyance entirely uncalled for and unnecessary.

One other subject of importance was discussed, that, viz., of unqualified attendance. That this is a serious evil cannot be denied. Under the system as it at present prevails, a qualified practitioner, zealous less for the honour of his profession than for the balance in his favour at his banker's, many registered medical men put their name over several shop doors, and then paying occasional visits to these places, and very occasional ones to the patients attracted thereto, leave the practice attached to them entirely in the hands of men placed in charge, and who are almost invariably unqualified for the work. In case of death occurring to any of the patients under treatment, a certificate of its cause is made out by the unqualified man, and then signed by the qualified master, without his having often the slightest acquaintance with the subject of it. It is useless to urge that these cases are met by an Act in force now, providing that any practitioner signing the death certificate of a patient not actually attended by him renders himself liable to heavy fine. Until a stop is put to the practice of multiplying surgeries in charge of unqualified assistants the evil will not be met; and we do not see that this measure is outside the legitimate scope of labour of the medical committee that will draw up a memorial on the relations between coroners and medical men. The question is one nearly affecting their interests, and bears directly on uncertificated deaths. Being so, it is worthy of notice in connection with the subject of registration.

In a short time we shall have before us the official report of the meetings already held, Drs. Danford Thomas and Stevenson having been deputed to prepare it. We shall then be better able to discuss the proposed alterations in existing laws.

◆

# Notes on Current Topics.

## The New Director-General, Navy Medical Department.

The appointment of Dr. J. W. Reid to the post of Director-General of the Navy Medical Service will be productive of unmixed good to this much degenerated branch of the profession. The unenviable condition into which the post of navy surgeon has fallen reflects considerable disgrace on the administration by whose laxity and carelessness the existing state of things has been brought about. So bad that it could scarcely be worse, the least appreciable change for the better will be magnified by contrast to such an extent that a new danger arises, lest the improvements about to be inaugurated may not be unduly warped in the extent of their possible effects. Under the spirited and determined lead of Dr. Reid, however, no doubt need be entertained that the reforms instituted will be of the most thorough character; and so far as his influences is able to effect desirable changes in the department, it will be exerted persistently and unfalteringly. It is to be regretted that the new Warrant has not been issued as a guide to men who contemplate embracing the opportunity of entering the naval service ; but it is only generous to anticipate that the Admiralty will not be backward in following the good example so lately set by the allied service.

## Charing Cross Hospital.

We are glad to note that the students with the cooperation of certain members of the staff, of Charing Cross Hospital, gave a musical and dramatic entertainment, on Tuesday last, in the Board room. The performances were got up to afford an evening's amusement to a number of the patients ; but invitations were also issued to many friends interested in the institution, the result being the assembly of "a brilliant gathering." The entertainment was a signal success, and we trust it will be an encouragement to the initiators of it to repeat the experiment on future occasions. These *réunions* producc undoubted benefit to the hospital in which they take place, by exciting the interest of friends, who are thus brought into direct association with it, and the work going on within it ; and by extending the circle of those who become personally acquainted with the active organisation of our great charities, it stimulates a healthy public feeling in their behalf. The example set by Charing Cross and the London Hospitals may be followed with advantage in other places.

## Tight-Lacing.

There can be small doubt that the great majority of women submit themselves to a waist-compression that exerts a very injurious influence on their health ; and it is by no means improbable that the greatly increasing numbers of sufferers from the heterogeneous class of ailments termed "diseases of women" are augmented chiefly in consequence of the unnatural distortion to which women submit themselves in pursuit of the phantom "fashion." The importance of giving due consideration to this practice, and the evil effects following from it, are insisted on by Dr. Dyce Duckworth, in the January number of the *Practitioner*. Dr. Duckworth does not incline to think that the ill-consequences of the practice are likely to be so severe in the future as they have been in the past, but in this he may be possibly mistaken. The changes which have been made in the shape of the corset within the last ten or twelve years, by the introduction of a form of stay termed the "spoon-busk," and which exerts pressure directly on the lower portions of the abdomen, have, we venture to believe, been largely to blame for the great prevalence of uterine displacements, the frequency of which among young people of the better classes has been more than once commented on by practitioners. It will be well if the profession take the advice given by Dr. Duckworth, and give increased heed to the possible consequences of a "fashionable attire."

## The Irish Prison Surgeons.

We understand that the "Departmental Committee" to which was relegated the dispute between the Irish Prison surgeons and the General Prisons Board, has agreed to its report, and forwarded it to the Government.

We may, therefore, assume that the question whether the prison medical officers are to receive the justice which the law has given to them or, on the other hand, are to be the victims of bureaucracy, is in course of settlement. The decision of the Government will, without doubt, be greatly influenced by the feeling of their parliamentary supporters, and by the prospect of having to answer, in the House of Commons, for the conduct of the Irish Prisons Board, and we therefore consider that the present is the critical time in which the best influence of prison surgeons over their parliamentary representatives ought to be exercised. If the surgeons do not think it worth their while to put out their energies in this way they must be content to be sacrificed without mercy to departmental despotism. If they do, they will find, we think, no difficulty in persuading their city and county members that it is a substantial grievance that they have remained from the 30th of November, 1877, to the present hour without a shilling of pay, and without any definite arrangement for the performance of their duties.

## Local Temperature in Surgical Affections.

At a recent meeting of the French Academy of Medicine M. Broca read an interesting communication on local temperatures. He had been struck by the contradictory opinions expressed by various authors respecting the local temperature of limbs after ligature or obliteration of the main artery, but these diversities of opinion he considered were due to the observations on which they were founded not having been all made under similar conditions. In an experiment which he had made in which the femoral artery was digitally compressed in the fold of the groin, there was a fall of temperature of 4° during the first 44 minutes. The temperature then remained stationary for about 10 minutes, and then rose 2°, up to the end of the experiment, which lasted 84 minutes.

Investigation of local temperature enables us to say whether an interference with the circulation of an artery is due to embolism or an arteritis. Supposing there is an embolism of the femoral in the middle of the thigh, by applying 3 or 4 thermometers in the length of the leg, and the same number on the other limb for comparison, we should find equal temperature at the upper part of the thigh of both limbs, increase at the level of the embolism, equality again a little lower, and diminution still further from the obliterated spot. If there were endarteritis there would be uniform diminution. In taking local temperature in cerebral cases M. Broca employs a kind of thermometric crown. In acute softening he has found increase of temperature of 3°. Chronic softening from atheroma on the other hand caused a lowering of temperature. One result of M. Broca's is curious—he has found that an elevation of temperature on the frontal region is caused by intellectual work. In torticollis he found a difference of ·4 of a degree on the side to which the head inclined. In cases of embolism of the Sylvian artery there was lowering of temperature in the temporal region, increase in the frontal, and slight increase in the occipital.

---

At the annual meeting of the Society of Public Analysts held last week at the University of London, Dr. Muter was unanimously re-elected president of the society.

## The Anti-Vaccinators at Limerick.

The Guardians of the Limerick Union have been obliged to order a sixth prosecution of a Mr. Jacob, a refreshment-house keeper in the town, for refusal to have his child vaccinated. Much as the necessity for repeated prosecution is to be regretted, we must commend the determination of the Guardians to do their duty by carrying into effect the law entrusted to them. It is not for them to decide upon the arguments of the anti-vaccinators, nor would they be even justified in refraining from prosecution if they believed that the effect of the enforcement of the law would be to increase the number of those who refuse to obey it. These considerations are for Parliament, not for Guardians, and they have been decided upon more than once by Parliament, the decision being always—as it must be when the facts are investigated—dead against the anti-vaccinators. The case against compulsory vaccination is to be found in any one of a multitude of pamphlets issued by the Anti-Vaccination Society, and consists in the endless repetition of assertions which are quite untrue, interpretations of facts so distorted as to be wholly fallacious, unutterable bosh of a pseudo-religious nature, and attempts at logic which prove nothing. No one who knows anything about the subject, who reads anything about it in reliable books, or who thinks about it without prejudice, could be persuaded by anything these pamphlets contain; but then Mr. Jacob and his cogeners are not of the class who either think or read anything except what satisfies their prejudices, and who would not for worlds accept enlightenment, lest they might learn how ignorant and how foolish they have shown themselves. Such people must not be permitted to turn the current of the law or of scientific inquiry, and, however much some good-natured people may pity them and respect them for the apparent disinterestedness of their stupid self-immolation, they must be forced to conform to the law as all the world does. We have no such pity or respect for vaccino-martyrs, for we believe that all their ostentatious self-sacrifice is only the price which they pay for notoriety and for the admiration of *gobe-mouches*.

In politics we have ample experience that, for agitators of the martyr class a grievance is a necessity to their comfort, yea, often even to their daily bread, and that if you satisfy their clamour by giving what they ask, they must fly to new grievances or starve.

Vaccination is a handy grievance for Mr. Jacob, but if Parliament yielded to his fire and fury oratory and to-morrow abolished vaccination, he could not exist for a month without some other means of obtaining notoriety. If small people crave greatness and have not the brains or industry to achieve it, they must get it by putting on singularity. But if Mr. Jacob must be singular, we have a right to ask him to choose some method which will not propagate disease or endanger the lives of his family—that's all.

## Poisoning by Aniline.

Three cases of poisoning having taken place in M. Lailler's practice, as a result of the application of a solution of hydrochlorate of aniline to patches of psoriasis, M. Leloir has made some experiments on the effects of aniline on the economy. The patients showed various symptoms of asphyxia, dyspnœa, cyanosis, fall of temperature, cramp, &c. The urine was scanty, red, contained fuchsine, and nothing but fuchsine.

The animals experimented on showed epileptic phenomena, as well as those of asphyxia. Injection of two grammes of hydrochlorate of aniline into the saphena vein of a dog weighing eighteen pounds, produced at first two or three strong inspirations, then opisthotonos, and lastly, a period of clonic convulsions, accompanied by salivation and dilatation of the pupil, and followed by almost absolute loss of voluntary movement.

Each injection of two grammes produced the same phenomena. Small doses produced only symptoms of asphyxia. A few hours in the first case were enough to cause death, which occurred during an increased asphyxia. M. Leloir believes that in aniline poisoning the animal does not die either by the lungs, by the heart, or by lesion of the nervous system, but by a primary action on the blood. The blood, indeed, shows some time after the injection a violet-brown colour.

## The Vacant Commissionership of Irish Poor-law.

Mr. R. M. Bellew, the second Local Government Commissioner for Ireland, whose serious illness we recently announced, is dead, and his office, with the attached £1,200 a-year, is vacant. We have good reason to know that the alarm which we then raised as to an impending job which would introduce to the department another sinecure office-holder, was not a moment too soon. There is imminent danger, we understand, that Mr. George Morris, M.P., may be appointed in Mr. Bellew's place, he being a gentleman who has done a good deal of message running for the Irish government, and who knows or cares as much about the Irish Poor-law as he does about Bulgaria. After the audacious job recently perpetrated in London of putting into the office of Registrar-General for England an ex-captain of the Horse Guards over the head of the greatest vital statistician in the empire, we cannot doubt that the present Government is capable of any transaction of the sort, and will not be deterred from jobbing the Irish Poor-law commissionership by any consideration of what is good for the public service, or honest towards the country.

We protest in the name of the medical profession against the nomination of any mere place-hunter to so important an office.

We do not speak on behalf of any candidate (though we know that a gentleman, who is thoroughly conversant with Irish local government, and who has shown great ability in its administration, has been named for the vacant office), but we have a right to ask, and we do ask, that the successor to Mr. Bellew shall resemble that gentleman as little as possible, shall have some knowledge of the service which he is to administer, and be disposed to give to the public some valuable service for his salary. The Irish Local Government Board needs reinforcement and not depletion, and it would be a grievance and a calamity if it be sacrificed to the necessity for providing for a mere political jackal. For Heaven's sake let Mr. George Morris have some neat little legal sinecure where his inertia will do no one (except the taxpayer) any harm, and let the

Irish Local Government Board have the aid of some man who has a little knowledge of its work, and some desire to do his duty actively and honestly.

### The Influence of Phosphorus on the Urinary Secretion.

M. P. Cazeneuve in a note read before a recent meeting of the Academie des Sciences, says that after a series of experiments on the dog and cat, he has come to the conclusion that phosphorus in toxic doses causes increase of urea, phosphoric acid, sulphuric acid, nitrogen, and iron. The destruction of blood corpuscles supposed to take place in phosphorus poisoning may be explained by the increase of excreted material. These experiments are important with respect to the function of the liver, as some physiologists regard this organ as the principal agent in the formation of urea.

### Lead in Butter and Confectionery.

The employment of chromate of lead to give an attractive yellow colour to butter has long been known, says *Le Praticien*, but recently Dr. Galippe has shown that the same substance is used in some confectionery to give the yellow colour which should be supplied by the yolk of eggs. A sample of this confectionery was brought before the Academy. Analysis showed that in a brioche weighing about 100 grammes there were 7½ centigrammes of oxide of lead.

### A Grain of Oats Passing through the Eustachian Tube.

The *Berlin Klinik* relates a case of a woman holding an ear of oats in her mouth who swallowed a grain. She soon felt a pricking, scratching pain on the right side near the base of the tongue, which gradually rose higher and higher. The pain increased, and there ensued suppurative inflammation of the middle ear with perforation of the membrana tympani. The grain appeared in the opening, and could be seen from the meatus; its removal was followed by immediate recovery.

### Chloral.

As confirming the views we have frequently expressed that the evil effects of free trade in chloral are under-estimated, we are glad to be able to quote the following from the *Cincinnati Medical Journal*:—

> "Not a week passes but we read of a death from the action of chloral, which has been taken as an anodyne, or for other medicinal effects. A peculiarity of the destructive action is that a person accustomed to the use of the agent is as liable to ill effects as an individual who has never employed the chemical previously; and it is also a fact that a moderate-sized dose will kill a patient who has tolerated large doses on previous occasions. In other words, experience in the use of the drug furnishes no safe rules for its administration. Probably a peculiar chemical state of the contents of the stomach has much to do with the action of the remedy. Chloral being now sold by the apothecaries to the non-professional *ad libitum*, and 'nervous people' being in the habit of swallowing the drug for the temporary relief of their multiple disorders, we may reasonably expect an increase of sudden deaths in every community until legal enactments place the use and sale of the dangerous agent under restraint."

We may not perhaps accept entire the dictum of our American contemporary, especially in the rather "mixed" theorising it indulges in to explain the toxic effects of the drug; but the note is an evidence that the uneasiness felt in respect to the injuriousness of chloral is not confined to this country. We can add that another instance of chloral poisoning has just come under our notice, the victim being a medical man.

### The Hendon Tragedy.

The conspicuous character attaching to the discovery of a mutilated man's body at Hendon has excited a good deal of animated discussion in medical circles. The verdict, "suicide while temporarily insane," does not seem an improper one in the face of a complete absence of evidence tending to criminate a second person; and more, the peculiar nature of the wound proving that the cutting must have been a somewhat long operation, together with the appearances that the unfortunate man had dragged himself some distance after the act, and then precipitated himself from a bridge, tend together to force conviction that the case was not one of murder. Self-immolation is by no means an unknown occurrence, and it is not difficult to imagine a morbid condition of mind resulting in an act like that of Sibley's, and dictated by phantom fears of premature senility. The removal of all the external genital organs need not necessarily prove fatal, for we remember a case to the contrary. A youth, while swimming in Falmouth Harbour, was suddenly attacked by a large fish—possibly a young shark—which, rushing between his legs, bit away the penis and scrotum with its contents. This person recovered, being possibly aided thereto by the styptic action of the sea water. On certain minds the deadly horror experienced at the thought of emasculation is, in itself, enough to nerve the heart for the commission of any deed, and it is not at all opposed to the teachings of experience to conclude that the mystery of the late Hendon tragedy is resolvable on this explanation.

### Hysterectomy at the Richmond Surgical Hospital.

On Wednesday, the 14th inst., Mr. William Stokes performed the operation of hysterectomy on a patient æt. 48, and removed a uterine tumour of enormous dimensions, weighing over 20 lbs., together with both ovaries. The tumour first appeared about eleven years ago, shortly after the birth of the patient's last child. The diagnosis made previous to the operation was fibro-cystic tumour of the uterus, with probably ovarian disease. The patient rallied well after the operation, which owing to the unusually large size of the tumour was attended with extreme difficulty; but on the evening of the second day the patient exhibited signs of failing, and early on the morning of the third day after the operation she sank, apparently from shock and exhaustion. Mr. Stokes detailed the history of the case, and exhibited the tumour to the Pathological Society, at the meeting held last Saturday, and the specimen was referred to the morbid tumour committee for further examination.

### Internal Use of Tar.

In a recent number of the Berlin *Klin. Wochenschrift*, Prof. Reclam, of Leipzic, reports some therapeutic experiments with tar. He used it in pills or capsules, and says that tar water is not so efficient. One curious and constant effect noted was that the urine of a patient taking tar does not decompose for five or six days, instead of in twenty-four hours, as usual. The general indication for tar, he says, is a chronic catarrhal inflammation of the mucous passages of the respiratory or urinary tract, as bronchitis, vesical catarrh, gleet, &c.

### The Frog Cure.

In *De Tydschrift*, a Dutch journal published at the Cape, an old lady recapitulates a list of remedies with which she tried to cure some affection of the lungs. "I began," writes she, "with ordinary plasters, then thorn plasters, then tar plasters, then Holloway's ointment, then Poor Man's Friend, pipe oil, Haarlem oil, and the 'lights of a young kid.' Failing to receive the least benefit, I next tried in succession wild dagga, blue gum, buchu, peaches, wild aloes, kruidje-roer-mij-niet, and they failed. Then I tried one-half of everything in a big Huis Apotheek, and still failed to get cured. An old woman advised me to boil the entrails of a sheep and drink the water. I did so but received no benefit. A 'Kanny Schot,' who said he was a doctor, tried carbolic acid and linseed meal, but it was the eight frogs in a muslin handkerchief that cured *me*."

### Statistics of Foreign Bodies in the Brain.

Dr. Wharton, in the *Philadelphia Medical Times*, gives statistics of 316 cases of foreign bodies in the brain gathered from different journals. Of these 316, 156 were fatal; 160 survived, 111 of whom were completely cured, and 49 remained affected with epilepsy, vertigo, blindness, deafness, paralysis, &c. The foreign bodies were extracted by surgical means in 106 cases (34 deaths, 72 recoveries), operation was not attempted in 210 cases (122 deaths, 88 recoveries). Of the 111 cases entirely cured, 56 were operated on, 45 not. In 7 cases there was hernia cerebri, 3 fatal, 4 cured. The lesion was in the anterior part of the cranium in 132 cases (58 deaths, 74 recoveries); in the posterior part in 23 cases (16 deaths, 7 recoveries); in the temporal region in 31 cases (12 deaths, 19 cures). The foreign body had penetrated by the orbit in 18 cases (17 deaths, 1 recovery); the sphenoidal region was lacerated in 5 cases (4 deaths, 1 recovery). Forty-nine times the part in which the lesion occurred was not clearly specified: of these there were 22 deaths and 27 recoveries. In 53 of the cases where necropsy was performed, death had taken place from the formation of an abscess in the brain. The other causes of death were inflammation of the brain and its membranes, pressure of the foreign body on the vessels or nerves, apoplexy and convulsions. The cases of coma all terminated fatally.

### Decalcified Bone Drains.

We are informed that Mr. Wheeler, of Dublin, employed Dr. Neuber's decalcified tubes in a case of amputation of the arm on Tuesday, the 13th, and states that it has acted to his satisfaction. We believe this is the first time they have been used in Dublin since their recent introduction into surgery.

### Injection of Chloral in an Erectile Tumour.

Dr. A. Pupi, in *Lo Sperimentale*, narrates a case of erectile tumour treated by parenchymatous injection of chloral. The tumour was in the naso-palpebral region, and had extended rapidly. After considering the various methods possible for its removal, Dr. Pupi decided to adopt injection of chloral, remembering that it coagulates the blood, is a hæmostatic and cicatrisant. Three injections were made at intervals of a fortnight, into the substance of the tumour. The proportion of chloral was 10 per cent. in distilled water. Each injection was immediately followed by swelling, which however was not painful, and disappeared in four or five days. The cure was complete, and scarcely any traces of the tumour can now be seen.

### Administration of Castor Oil.

The following method of administering castor oil is recommended by M. Potain, and described in a recent number of *Le Praticien*. An orange is cut in halves, and after removing the pips, the juice of one half is pressed out into a tea-cup. The oil is poured carefully on the top of this juice, and on this again the juice of the other half of the orange is squeezed out. The oil remains between the two layers of juice in the shape of a meniscus, and may be swallowed without any unpleasant taste.

### Quis Custodiet Custodes?

The *Chemist and Druggist* very cogently asks what have the College of Preceptors to say to this?

Mr. Thomas Marshall, of Charlotte Street, Fitzroy Square, writing to the *Times*, says: A few days since I received a midwife's certificate with the letters "M.R.C.P." written after the signature. Not being aware that women are admitted as members of the Royal College of Physicians, I wrote for an explanation, and received the enclosed reply to-day. I copy it *verbatim et literatim* for the information of your readers:—

"Dear Sir,—I simply signed my Educational tital. I am a meber of the Royal Colledge of Preceptors.—Yours respectfully, ——."

### Effect of Sugar on the Teeth.

If we are to believe M. Lerez, whose views are published in the *Charleston Medical Journal*, the ancient prejudice against sugar is not without good ground. The conclusions of M. Lerez are as follows:—"1. Refined sugar injures teeth—either by immediate contact, or by gas developed in the stomach. 2. That a tooth soaked in sugar-water becomes jelly-like, from the sugar combining with the lime of the tooth."

Sir Joseph Fayrer, K.C.S.I., is the newly appointed Examiner for the Army Medical Service in Anatomy and Physiology, *vice* Mr. George Busk, F.R.C.S.

Dr. Curnow, of King's College Hospital, has been elected to the post of Visiting Physician to the Seamen's Hospital, Greenwich, vacant by the death of Mr. Harry Leach.

Another sad instance of the danger to which the public expose themselves by familiarity in the use of drugs occurred last week at Doncaster, where a young woman was poisoned by taking an overdose of morphia. She was subject to fits, and took this drug to procure sleep. On the last occasion the first dose did not act, and a second was taken, producing sleep from which she never woke.

Last week the rates of mortality per 1,000 in the principal large towns of the United Kingdom, were—Oldham 16, Norwich 18, Leicester 18, Leeds 20, Brighton 20, Bradford 20, Portsmouth 20, Sheffield 21, Sunderland 21, Newcastle-upon-Tyne 21, Salford 22, Edinburgh 22, Nottingham 23, Glasgow 23, Birmingham 23, Wolverhampton 23, London 25, Manchester 25, Hull 25, Bristol 26, Liverpool 28, Plymouth 35, and again the highest rate Dublin 41.

Last week the death-rate from the seven principal zymotic diseases ranged from 0·0 and 0·9 in Brighton and Oldham, to 6·3 in Hull, 8·1 in Dublin, and 12·5 in Plymouth. Measles showed exceptional fatality in Plymouth, Hull, Liverpool, and Nottingham. Diphtheria and whooping-cough also contributed to the high zymotic rate in Plymouth. Scarlet fever and whooping-cough were very prevalent in London. Small-pox caused 8 more deaths in London, 5 in Dublin, and 1 in Bristol.

In the principal foreign cities the rates of mortality, according to the most recent official weekly returns, were—in Calcutta 31, Bombay 39, Madras 34; Paris 28; Geneva 23; Brussels 39; Amsterdam 33, Rotterdam 34, The Hague 23; Copenhagen 36; Stockholm 19; Christiania 23; St. Petersburgh 42; Berlin 25, Hamburg 29, Dresden 28, Breslau 22, Munich 29; Vienna 28; Buda-Pesth 39; Rome 41, Venice 49; Alexandria 39; New York 23 per 1,000 of the population. Small-pox caused 64 deaths in Paris, against 27 and 56 in the two preceding weeks.

By the will of the late Dr. H. H. Stewart, of Dublin, founder of the Stewart Institution for Imbeciles, he willed and bequeathed a sum of £2,000 "to be paid to the Treasurer for the time being of the Stewart Institution for Imbecile Children, as an endowment in addition to the sums already given to the said Institution by him; and out of the surplus fund (whenever such there shall be) he authorised and empowered his said trustees, aided and assisted in their judgment by his said wife, in whose sound and liberal views he had every confidence, and as she knew his wishes, to allocate the same to such charitable purposes (educational or religious, and without regard to sect or party) as they shall think proper from time to time."

◆

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

The Mortality of Glasgow.—The deaths in Glasgow for the week ending Saturday the 10th inst. were at the rate of 23 per 1,000 per annum against the same figure in the preceding week, and 28, 24, and 24 in the corresponding periods of 1879, 1878, and 1877.

Rutherglen Death-Rate.—According to the report of the medical officer, Dr. Mackechnie, there had been, during the month of December, 18 deaths and 37 births in this burgh. The death-rate was 21·6 per 1,000, which was a great increase over that for the previous month, which was 12 per 1,000. This was attributed to the low temperature which prevailed, and foggy weather, which had greatly increased the deaths from diseases of the chest. There had been four cases of scarlet fever in one family, two of which proved fatal. There had also been five cases of typhoid fever, four of which had recovered, only one proving fatal. At the date of the report there was one case of scarlet fever in the burgh.

Registrar-General's Returns.—According to the Registrar-General's returns for the week ending Jan. 10th., the death-rate in the eight principal towns during that period was 22·1 per 1,000 of estimated population. This rate is 6·2 under that for the corresponding period of last year, and nearly the same as that for the previous week of the present year. The lowest mortality was recorded in Leith, viz., 13·3; and the highest, as usual, in Paisley, viz., 28·7. The mortality from the seven most familiar zymotic diseases was at the rate of 2·9 per 1,000. Whooping-cough, though still the most prevalent of these diseases, was less fatal than during the previous week. The death of a gamekeeper, aged forty-three years, who died in the Glasgow Royal Infirmary, was certified as due to hydrophobia.

Glasgow Lock Hospital.—The annual general meeting of the qualified subscribers to the funds of the Glasgow Lock Hospital was held in the Religious Institution Rooms on the 13th inst., Mr. Mathew Fairley in the chair. Mr. Robert Young read the 74th annual report of the directors, in which the sustained efficiency and utility of the institution were referred to. At the commencement of the year there were in the hospital 21 patients, and there had been admitted since 343, making in all 364. During the year 335 had been dismissed as cured, leaving 29 under treatment on the 31st ult. These figures showed a decided decrease in the numbers seeking the benefits of the institution. The average age of the patients did not exceed 22 years. The annual subscriptions had this year fallen short of the preceding year by £37, these amounting to £447 6s. 6d. The disbursements were much the same as last year. The directors urgently appealed to the citizens for increased contributions, and they also respectfully called attention to those who might have charge of suggesting and distributing legacies to the claims of the institution. New directors were appointed, and a vote of thanks to the medical officers terminated the proceedings.

Public Analyst for Perth.—Dr. Wallace, Glasgow, was appointed analyst for Perth, at a meeting of the Perth Police Commissioners, held on the 12th inst., at a salary of £40 per annum, and two guineas per day when his attendance is required at prosecutions.

Edinburgh Royal Maternity and Simpson Memorial Hospital.—The directors of this hospital have appointed J. Milner Helme, M.B.C.M., and Stanley M. Rendal, M.B.C.M., as house-surgeons for the quarter from 1st prox., in place of Andrew Murray Oram, M.B.C.M., and Charles A. Maclean, M.B.C.M., whose term of office then expires. Professor Simpson, who has been on duty since 1st November last, will be succeeded on 1st February by Dr. Angus Macdonald, as medical officer on duty.

The Action against a Leith Galvanist.—In this action, formerly referred to against D. (not Dr., as erroneously printed in former notice) Rintoul, Sheriff Hallard found for the pursuer, and in consideration that the hand and arm were previously in a damaged condition, thought £10 and expenses sufficient compensation. In a note his lordship says:—The two distinguished surgeons who saw the pursuer's hand practically concur in their opinion as to the result of the defender's treatment of it. Mr. Bell says that "the limb had been boiled and was dead." Dr. Littlejohn says, "I am not prepared to say that that would be an exaggerated phrase," and adds, "I am familiar with cases of death through scalding, and the pursuer's hand presented similar appearances." Now it is thought to be clear that in this case the maxim *spondet peritiam artis* applied to the extent of making the defender liable for the consequences of so gross a blunder as he committed in this instance. The question is not how far the hot water into which he so recklessly plunged the pursuer's arm and hand rose towards or fell short of 212 deg. Fahr., but whether, from want of care on his part, the diseased limb was put into water so excessively hot as to produce consequences which made amputation necessary. On that question it is thought that the evidence of practitioners, however eminent, who did not see the limb, cannot outweigh the evidence of practitioners, equally eminent, who did. And after going over the numerous authorities cited by counsel in the course of the discussion, the Sheriff thinks they are well summed up by this *dictum* in Bell's Com.:—"Under this rule (*spondet peritia artis*) all professional men are comprehended. Their contract is *locatio operarum*, not mandate; and they, as well as smiths, farriers, bleachers, and ordinary artists of all kinds, whenever they engage their services for hire, are responsible for the skill and art necessary to accomplish safely what they undertake, in so far as ordinary skill and art can accomplish it."

Glasgow Royal Asylum for Lunatics.—The annual general meeting of the qualified contributors to this Asylum was held in the Religious Institution Rooms on the 15th inst., the Lord Provost presiding. The secretary (Mr. J. Roxburgh Strong) submitted the sixty-sixth annual report for 1879, which stated that the asylum contained 532 patients of all classes at the commencement of the year. There have been 180 admissions, 136 discharges, of which 57 were recoveries, and 47 deaths, so that the number at the end of the year is 529. Of this total 226 are private patients, and 363 are chargeable to parishes, as against 189 private and 343 pauper patients at the beginning of the year. The decrease of 40 in pauper patients has been caused solely by want of room, which compelled the directors to restrict the admission of this class. The increase of 37 in private patients is partly due to the transference of 14 patients from the private asylum at Bothwell when that institution was closed. The directors have great satisfaction in reporting that the heritable debt which has so long burdened and hampered the institution is now extinguished. They congratulate the contributors and the public that this result, so long hoped for, has at length been obtained. Among the additions and improvements effected during the past year there may be mentioned two shoe-rooms properly heated for the out-door workers, and the erection of a covered passage from the west house to the large hall, which is thus easily accessible now from all parts of the house. The directors regret to record the death, in October last, of Dr. John Gibson Fleming, who has held the office of surgeon to the asylum since the year 1839. Dr. Fleming succeeded his kinsman the late Dr. Balmanno. He never ceased to take the warmest and kindliest intere stin the asylum. His best skill was always promply at its service, and the directors desire to place on record their sense of the loss which the institution has sustained. New directors were appointed, and a vote of thanks to the chairman concluded the business.

## TREPHINING OF THE SKULL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—On looking over the *Medical Press and Circular* of the 17th of December last, I observe that part of my remarks at the first meeting of the Surgical Society, and a case which I quoted that bore directly on the subject under discussion, omitted. I relate the case:—

Some years ago the servant of a general officer came under my care, who, when stooping to pick up something near a baggage mule, received a kick below the superior angle of the left parietal bone. The man was stunned, but there was no scalp wound, inasmuch as he was partially protected by a forage cap. He was treated by cold applications and purgatives. On the fourth or fifth day after the injury he had an epileptiform fit; he then came under my care, and was examined by myself and Surgeon-Major Chartees. We felt a slight depression, but there was scarcely any entravasation beneath the scalp, probably on account of being attended to so quickly after the injury; another fit occurred the day after, and we decided to trephine him; the lot fell on me. The inner table of the skull was found pressing on the dura mater, as also small separate quantities or points of blood. The patient made an excellent recovery and had no return of the fits.

In the *Medical Press* of January 7th, important points are left out in my descriptions (at the Surgical Society) of the diseased clavicle excised by me, and the "scirrhus mammary tumour."

The curtailed description of the former would give the idea that the bone lay comparatively loose, whereas I distinctly stated that the sterno-cleido-mastoid, trapezius, pectoralis major, deltoid, subclavius, and sterno-hyoid muscles were attached as well as the ligaments.

I stated the encapsuled scirrhus mammary tumour was examined by the College curator, Mr. Abraham, that there were no glands enlarged, that it had been growing for more than five years, that the lady I removed it from was sixty-eight years of age, that it was shown because it was encapsuled, and had a distinct connective tissue investing it, which on the high authority of Sir James Paget, was said not to exist in scirrhous cancer of the present.

Faithfully yours,

Jan. 17th, 1880. W. J. Wheeler, F.R.C.S.

## TRAFFIC IN ENGLISH PSEUDO-CHARITY VOTES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your comments on the above you have, unintentionally, I am sure, made a serious mis-statement regarding our proposed department (it is not in actual being) for the exchange of charity votes. We do *not* observe or even so much as suggest, that we might "as well make a little profit" out of an abuse which we admit. On the contrary, our object is to lessen the abuse, and at the same time to assist those of our readers who are interested in any of the various charities to which elections are made by the votes of subscribers. The quotatiom from our paper is misleading, for it is not taken from the full statement of our views, but is made up from the editorial notes to the letters of two correspondents, and should therefore be read with the letters themselves and with the editorial article which elicited them. I enclose the article, which appeared in our issue of Dec. 12, and I venture to think that if you will read it, you will admit that it places our action in a very different light to the one in which you have viewed it. As a matter of £ s. d. it makes no difference to us whether our columns are filled with one class of advertisement or another, and already each of our three issues weekly is filled to overflowing; but we do aim at being helpful and useful in every legitimate manner, and, for the reasons advanced in the article, we consider that we should be doing good service to the public by rendering the transfer of charity votes more easy and cheap than it has been hitherto.—I am, &c.,

LEONARD M. GILL.

## Obituary.

### DR. WILLIAM BUDD.

DR. WILLIAM BUDD died at his residence, Clevedon, Somersetshire, on Friday, the 9th inst. Dr. Budd was the son of a surgeon of North Tawton, Devonshire, and after a careful preparation under his father he went to Paris and continued his studies at the Ecole de Médicine and the Collége de France. He afterwards graduated at the University of Edinburgh, taking his degree in 1838, and in 1844 he obtained an appointment in Bristol as one of the physicians of St. Peter's Hospital. He was afterwards elected one of the physicians of the Bristol Royal Infirmary, and he materially helped forward the pathological museum which Mr. Richaad Smith had started. In consequence of ill-health he had to resign the chair of Practice of Medicine at the British Medical School, and in 1862 he gave up his appointment of physician at the infirmary. In 1870 he was elected a Fellow of the Royal Society. His principal work was his elaborate and exhaustive treatise on "Typhoid Fever, its Nature, Mode of Spreading, and Prevention."

◆

### DR. PAGENSTECHER.

THE death is announced of the well-known Wiesbaden ophthalmist, Dr. Alexander Pagenstecher. He was returning from a shooting excursion, when his breechloader, which was lying behind him in his sledge, went off, the ball passing through his head and mortally wounding him. He died a few hours after the accident. Dr. Pagenstecher, who was only 55 years of age, had long been director of the Ophthalmic Hospital in Wiesbaden.

◆

### DR. HUME.

THIS gentleman died on the 9th inst., at his residence in Crumlin, county Antrim, aged 60 years. Dr. Hume, whose health had been impaired for about a year, was a graduate in medicine of the University of Glasgow, and held the post of coroner for the Belfast district of the county Antrim for the past fifteen years, the duties of that important office being performed with ability. His practice was of an extensive kind, and he was a most popular and esteemed member of the community among whom he resided. Dr. Mussen of Glenavy is a candidate for the vacant coronership, and it is most probable that he will be returned without opposition.

◆

### MR. WILLIAM ALLEN.

ON Friday, the 9th inst., the grave closed over the remains of the late Wm. Allen, one of the most respected of the pharmaceutical chemists of Dublin. Mr. Allen's is the first name on the list of the twenty-one gentlemen selected by Government as the first Council of the Irish Pharmaceutical Society, and he is also the first of that body removed by death. Mr. Allen was 65 years of age. The funeral was very largely attended by members of the Masonic Order, of which Mr. Allen was a prominent member, having attained what is termed the 32nd degree, a position reached by few. The last monthly meeting of the Council of the Irish Pharmaceutical Society, after reading correspondence, was adjourned out of respect for the late member.

## Medico-legal Intelligence.

### FALSE CERTIFICATES.

ON Saturday last, at the Lambeth Police Court, Mr. James Bilham, M.R.C.S., of Brixton, was charged, "that he did unlawfully make a false certificate or declaration under the Births and Deaths Registration Act, 1874, concerning the death of Mary Anne Bowtell."—Mr. C. J. C. Pridham said he appeared to prosecute for the Medical Defence Association, acting under the authority of the Registrar-General. The defendant was a surgeon, whose address in the Medical Register was given as in the Harrow Road. At the address in Milkwood Road his name was up as well as in Saltoun Road, Brixton. In the last-named house a gentleman named Ransdon resided, who would be called in connection with the case. Mr. Ransdon, who saw the deceased woman, was an unqualified medical man. The certificate given by the defendant stated that the deceased, Mary Anne Bowtell, aged 75, died on the 9th December, and that he last saw her on the 8th December. This was signed by the defendant, who gave his address 12 Saltoun Road, Brixton.—Mary Renshaw, daughter of the deceased, stated that her mother was ill, and she sent for Mr. Bilham. The gentleman she saw in court, and whom she was told now was Mr. Ransdon, came and attended her mother. She always thought he was Mr. Bilham. He had frequently attended her and her children, and she believed him fully qualified. She had seen the defendant in company with Mr. Ransdon before her mother's death, and he had expressed an opinion that she would not last the winter through, as she was suffering from disease of the heart. He also said it was a case of senile decay.—Mr. Ransdon was called for the defendant, to whom he said he was an assistant. The defendant saw the deceased before her death. The witness added that his name was up at Saltoun Road. The defendant lived at Paddington, and during the two years he had been his assistant the surgery in Saltoun Road had been carried on. He saw the defendant sign the certificate of death.—After some further evidence, Mr. Ellison said, in deciding the case, it was no doubt one in which a false certificate had been given, but it was not one of those extreme cases in which a certificate was given and a false cause of death entered. There was no doubt the defendant had, on one or two occasions, attended the deceased, and had a certain knowledge of the case. He would not convict the defendant to the full extent the Act gave him power to do—viz., £10—but ordered him to pay a penalty of £5 and £5 5s. costs.

### A RETAINING FEE.

AT the Redruth County Court last week, a somewhat novel case was decided, in which Mr. C. H. Butlin, M.R.C.S., of Camborne, claimed 5s. from John Sims for bespeaking attendance on his wife in her confinement.—His Honour asked if medical men could recover on retainers?—Mr. Butlin said they could; it was a custom of the profession.—Defendant said Mr. Butlin told him to go to someone else as he could not pay the booking fee of 5s. He did not get someone else, but an old woman attended his wife out of kindness.—Mr. Butlin said never in his life did he refuse to come because the money was not paid.—His Honour: It's not very likely. Judgment for plaintiff, payable in 1s. a month.

◆

## Literature.

### ESSAYS ON OPHTHALMOLOGY. (a)

MR. G. E. WALKER, whose name is well and favourably known in connection with ophthalmic surgery, opens his interesting "Essays on Ophthalmology" with the following quotation from a recently published work on "Diseases of the Eye":—"Against glaucoma in all its forms, and from their commencement to their termination, the resources of the Pharmacopœia are utterly useless. They are worse than useless, for their employment wastes time and loses opportunity. The only remedy for the disease is the operation of iridectomy." Such dogmatic teaching is, we are bound to say, in no way justified by experience. It is not surprising, therefore, that Mr. Walker should demur to it, although it has become the fashion to resort to iridectomy in almost every conceivable form of disease of the eye, pigmentary retinitis not excepted, and if in any given case the eye is lost it is, of course, rather the fault of the eye than of the operation.

---

(a) "Essays on Ophthalmology." By George Ed. Walker, F.R.C.S., &c. London: Churchill. 1879.

Mr. Walker, like some other of his brethren, has put iridectomy to the test of experience, and found it wanting; indeed, he goes so far as to say that, in his opinion, "the removal of a large piece of impeccant membrane without explicable cause is repulsive, if not often destructive to vision. When we consider what an important part the iris plays in health, and what a potent agent of mischief it is in disease, we cannot but be lost in amazement that such a free mutilation of it should be advised and practised, and considered harmless. Future generations of physiologists and ophthalmologists will surely stand aghast at the way in which the iris has been cut about in the last quarter of a century." This is strong language, and may be looked upon as the vapourings of a disappointed man, and which is probably not very far from the truth. Nevertheless much can be fairly urged against the resort to iridectomy for many and very opposite diseases of the eye; and as to its physiological or curative action, who can satisfactorily explain it. Its originator could not, and the last solution offered is that, by tearing or cutting away a portion of the iris, we relieve tension by producing a "cicatrix of filtration," whatever this may mean, for it is scarcely intelligible to see how "filtration" by either permeable cicatrix or actual fistula can afford relief to a glaucomatous eye. In fact, neither Von Graefe nor his disciples have been able to offer a sound, much less a scientific, explanation of the action of iridectomy. They, therefore, speak of their master as one to whom the twofold credit is due of having perfected a system of eye diseases (the common bond of which is increased tension or hardness of the eyeball) and as having originated a simple and certain cure in iridectomy.

On looking a little more closely into Graefe's writings, it is at once seen that this is far more than he himself claimed. He was cautious, and certainly did not look upon "the resources of the Pharmacopœia as utterly useless." He rather inculcated "waiting, in certain cases, so that, if the inflammation tended to abate, and the sight to improve somewhat *under the treatment*," no operation need be performed. He further added that "the urgency (for an operation) does not depend on the intensity of redness, or chemosis, nor the *amount of tension*, or pain, but rather on the degree of impairment of vision." This sensible advice is now apparently quite disregarded, and the upshot of it is that patients are frequently subjected to operation without hesitation in the consulting room.

Mr. Walker's experiences of iridectomy are not of a favourable nature, and he has thus been led to look about him for a simpler and more rational method of treating glaucomatous affections, and at length he found one in a modified form of "section of the ciliary muscle"—an operation which is regarded by iridectomists with as little favour "as the resources of the Pharmacopœia." Mr. Walker calls his operation "hyposcleral cyclotomy;" his method of performing it is as follows:—The patient being fully etherised, and the lids separated by the speculum, he pinches up a fold of conjunctiva with the toothed forceps slightly to the inner side of the vertical diameter below, and then thrusts perpendicularly through the cornea well within transparent tissue, a very narrow knife, edge upwards, exactly opposite to the point held by the forceps. Then depressing the handle, so as to bring the knife-edge parallel to the curve of the tunics, it is made to cut through the iris, and is slowly withdrawn, and made to cut its way out up to the sclerotic. As the return incision is made a distinct sensation is felt as of cutting a gristly body. The pupil, which, up to this time, is of a medium size, is at once dilated towards the wound, and then all round. The eye is bound up, but little or no after treatment is needed. The operation itself is, Mr. Walker believes, facilitated by the previous use of a half-grain solution of eserine, which in his hands has proved most successful. This success, he thinks, is due to "the immediate relief of tension and infiltration, and for a time, the compulsory rest of the ciliary muscle." It must not be supposed, however, that cyclotomy can be likened to iridectomy; the two operations, which at first sight appear somewhat alike, are really very different. Mr. Walker satisfactorily, we think, proves this in his discussion of the "causation of glaucoma." He looks upon a half or one-sixteenth of a grain solution of eserine as a valuable remedy in the treatment of the chronic stage of the disease, and furnishes particulars of a number of interesting cases.

We must add that his volume is by no means entirely devoted to the consideration of glaucomatous affections of the eye. On the contrary, he offers practical observations on the treatment of exophthalmos, gonorrhœal ophthalmia, neuro-retinal atrophy, and sympathetic ophthalmia. There cannot be a doubt that he has acted wisely in yielding to the advice of friends to give to his professional brethren the benefit of an extended and valuable experience in eye surgery.

## TRAFFIC IN PSEUDO-CHARITY VOTES.

We have read the letter which our correspondent has kindly forwarded (*vide* correspondence column), and are obliged to say that it seems to us greatly to strengthen our protest against the proposed systematic traffic in charity votes. The editor of the *Exchange* opens his proposition by saying] that he contemplates establishing a column for the "exchange and *purchase* of charity votes." There is no mincing the matter. But he has waited in expectation of "such changes as would remove some of the undoubted evils of the present system." This latter phrase might be read to indicate changes which would put a stop to the most deplorable and corrupt traffic already existing; but, continuing our perusal, we find that the editor's idea is that the buying and selling of charity votes is not sufficiently open, and as the distillers would remedy the abuse of liquor by freeing it of all tax, and allowing all the world to sell it, so the editor would remedy the illicit sale of votes by vending them openly to the highest bidder for anything they will bring.

We fear we shall not agree with our editorial *confrère* in this matter, for we hold the old-fashioned idea that any person who has a voice in the distribution of public charity is bound in common honesty to apply the benefits of that charity to the most deserving person. He who imposes upon a charitable fund a person whom he knows to be undeserving, simply, in our view, steals a certain yearly sum from its coffers, and he who aids another person by his vote in doing this, in consideration of the other person helping him to repeat the imposition upon some other charity, is doubly guilty. While we live in the existing atmosphere of charity corruption, in which the money of the benevolent is hourly misappropriated by selfish persons, we suppose our views will be considered as high-flown and uncommercial. While we hold them we are certainly bound to protest against any journal making its columns attractive (if the word "profit" be objected to) by aiding selfish and unprincipled people to prostitute the objects of charity to their own uses.

## THE HEALTH OF IRELAND.

The mortality, last week, in 20 large English towns, inclusive of London (in which the rate was 25·0), was equal to an average annual death-rate of 24·0 per 1,000 persons living; in Glasgow the rate was 23·6; and in Edinburgh, 22·3.

The average in the sixteen principal Town Districts of Ireland was 34·1, the respective rates being—Sligo, 15·0; Galway, 15·8; Waterford, 17·0; Drogheda, 20·9; Dundalk, 25·6; Belfast, 28·0; Cork, 28·8; Newry, 30·1; Clonmel, 31·5; Limerick, 31·8; Queenstown, 32·5; Wexford, 34·4; Dublin, 41·0; Kilkenny, 42·1; Londonderry, 60·6; and Lurgan, 77·4. With reference to the high death-rate for the two last-named districts it should be stated that 10 of the 36 deaths registered in Londonderry, and 17 of the 23 deaths in Lurgan occurred in public institutions, and that the returns do not afford information as to whether any of these deaths were of persons admitted from localities outside the registration areas adopted. No case of small-pox is reported from any of the provincial towns. Eight deaths from scarlatina and 6 from measles were registered in Cork; in the preceding week there were 14 deaths from the former, and 8 from the latter disease recorded in that district.

In the Dublin district the deaths represent an annual rate of mortality of 41·0.

There were 56 deaths from zymotic diseases registered, being 3 more than in the preceding week, and 16 over the average number for the first week of the last ten years: they comprise 5 from small pox, 11 from measles, and 10 from scarlatina.

The registered deaths from small-pox (5) are one over the number of the preceding week, but the new cases of the disease admitted into the Dublin hospitals, which in that week amounted to 36, fell to 24 last week.

◆

## NOTICES TO CORRESPONDENTS.

**Reading Cases.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**Dr. Flinn, Lichfield.**—1. The appointment is no doubt most unjust, but we fear it would be useless on your part to protest, as the parties concerned do not appear to have overstepped legal bounds. 2. We entirely agree with you that the sale of practices to unqualified practitioners, or the purchase of practices from such men, is most reprehensible, and not calculated to uphold the dignity of the profession in the eyes of the public.

**Ethnologist.**—We know of no good modern work on the subject.

**A Lady Superintendent.**—We understand that the whole of the staff at Guy's are against the innovations of the lay treasurer and his nominee.

**Clinical Society of London.**—On Friday, January 23: Mr. Pick, "A Case of Sub-astragaloid Dislocation." Dr. Hewan (for Mr. Adams), "A Case of Bullet-wound of the Lung."—Dr. Habershon and Mr. Davies-Colley, "Pyelitis: Discharge of Pus: Incision in the Loins: Recovery."—Dr. Habershon, "Chylous Urine after Ague in India: Albuminuria: Cessation of Chylous Urine with the Development of Glycosuria and Polyuria."—Dr. Pavy will exhibit a Modified Form of the Copper Test for Sugar, specially adapted for clinical use.—Dr. Sturge will show Two Cases of Trade-Neurosis.

**Dr. Smythe, Greencastle, Indiana.**—Many thanks.

**Dr. Yandell, Louisville, Kentucky.**—We will make inquiries.

**Dr. Byrd, Quincy, Illinois.**—Our publisher has been instructed to send you the back numbers.

**Mr. J. W. H.**—The communication is such a palpable advertisement that it can only be admitted into the columns devoted to announcements of the kind.

**Army Medical Service.**—We are asked to mention that the list will be closed to intending candidates on the 31st inst.

**Pharmacist.**—The recipe of Holloway's Pills, published in a chemical paper some time since, was not quite correct. We believe each 100 parts by weight of the pill mass is composed of 40 parts aloes, 20 rhubarb, 18 ginger, 5 cinnamon, 2 saffron, 5 sulphate of soda, and 10 parts of sulphate of potassa.

◆

## VACANCIES.

Birmingham General Hospital.—Registrar and Pathologist. Salar £130, with board and residence. Applications to the Hon Governor before Jan. 26.

City of Dublin Hospital.—House Surgeon. Salary, £100, with allowance. Election, Jan. 26. (See Advt.)

Glamorgan Infirmary, Cardiff.—Assistant House Surgeon and Dispenser. Salary, £50, with board. Immediate application to the Secretary.

Hungerford Union.—Medical Officer for No. 3 District. Salary, £80, with the usual extras. Applications to the Clerk of the Union before Feb. 10.

Kenmare Union, Sneem Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, Feb. 3.

London Fever Hospital.—Physician and Assistant Physician. Applications, with testimonials, to the Secretary, Liverpool Road, Islington, by Feb. 7.

Middlesex County Lunatic Asylum.—Assistant Medical Officer in the Female Department. Salary commencing at £150, with board, &c. Applications to the Medical Superintendent before Jan. 27.

New Winchester Union.—Medical Officer. Salary, £100, with the usual extras. Applications addressed to the Guardians, St. Peter Street, Winchester, before Jan. 30.

North Dublin Union.—Medical Officer to the Workhouse. Salary, £150. Applications to the Clerk of the Union before Jan. 27. (See Advt.)

Portsmouth Hospital.—House Surgeon. Salary, £100, with board. Applications to the Chairman of Committee, The Vicarage, Portsmouth.

◆

## APPOINTMENTS.

**Brock, W. J.**, M.B., C.M., Assistant Physician-Accoucheur to the Glasgow Maternity or Lying-in Hospital.

**Brown, W.**, M.B., House Surgeon to the Gloucester General Infirmary and Gloucestershire Eye Institution.

**Coutts, J.**, L.F.P.S.G., Medical Officer and Public Vaccinator for the Parish of Kirkcowan, Wigtonshire.

**Dobson, A.**, L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the West District of the Holbeck Union.

**Forsyth, R.**, M.D., C.M., Medical Officer and Public Vaccinator for the Tong District of the North Bierley Union, Yorkshire.

**Morrissy, E.**, L.R.C.S.I., L.K.Q.C.P.I., Medical Attendant to the Royal Irish Constabulary, Kingscourt, co. Cavan.

**Ormerod, J. A.**, M.B., M.R.C.P.L., a Physician for Out-patients to the Great Northern Hospital.

**Percival, G. H.**, M.B., M.R.C.S.E., Medical Officer for the St. Andrew District of the Northampton Union.

**Phillips, S. P.**, M.B., M.R.C.S.E., Surgical Registrar to the Middlesex Hospital.

**Prosser, T. G.**, M.R.C.S.E., Medical Officer for the Monmouth District and the Workhouse of the Monmouth Union.

**Pyle, T. T.**, M.D., M.R.C.S.E., Visiting Physician to the Dinsdale Park Retreat Lunatic Asylum.

**Ransom, F. P. F.**, M.D., Medical Officer to the Workhouse and to No. 6 District of the Chesterton Union, Cambridgeshire.

**Rigden, B.**, M.R.C.S.E., Assistant Surgeon to the Canterbury Dispensary.

**Robinson, C. H.**, L.K.Q.C.P.I., F.R.C.S.I., Lecturer on Botany at the Ledwich School of Medicine and Surgery, Dublin.

**Moullin, C. W. M.**, M.B., M.A., M.R.C.S.E., Surgical Registrar to the London Hospital.

◆

## Births.

**Davson.**—On Jan. 15, at Mount Galpine, Dartmouth, the wife of F. Adams Davson, M.D., of a son.

**Ryan.**—At Castleconnell, co. Limerick, the wife of J. Ryan, L.R.C.S.I., of a daughter.

◆

## Marriages.

**Love—Rogers.**—On Jan. 7, by special license, at the residence of the bride's father, Andrew Thomas Love, M.D., Castlederg, co. Tyrone, to Sarah Elizabeth, daughter of John Rogers, Esq., Belfast.

**Peyton—Troup.**—On Dec. 16, at St. John's Church, Meerut, Bengal, Jones Lloyd Peyton, A.B., M.B., T.C.D., A.M.D., second surviving son of Reynold Peyton, A.B., M.D., Surgeon County Infirmary, Roscommon, to Annie Harriette, eldest daughter of the late General Colin Troup, C.B., Bengal Army.

◆

## Deaths.

**Beecroft.**—On Jan. 12, Samuel Beecroft, F.R.C.S.E., of Hyde, Cheshire, aged 59.

**Bradshaw.**—On Jan. 6, at Weston-super-Mare, William Hanna De la Maine Bradshaw, M.D., aged 33.

**Budd.**—On Jan. 9, at Clevedon, William Budd, M.D., aged 68.

**Daunt.**—On Jan. 15, at Bath, Mary Elizabeth, widow of Dr. Daunt late of Her Majesty's Army Medical Service, aged 81.

**Hume.**—On Jan. 9, at Crumlin, co. Antrim, George Alexander Hume, M.D., aged 60.

**Hurlstone.**—On Jan. 11, at Summertown Villa, near Oxford, Michael Oscar Hurlstone, M.R.C.S.E., Staff-Surgeon R.N., aged 39.

**Porter.**—On Jan. 9, at Sherpur, Joshua Henry Porter, L.R.C.S.I., Officiating Deputy Surgeon-General.

**Rankin.**—On Jan. 2, at Holles Street, London, Geo. Campbell Rankin, Surgeon, Bengal Service, Retired List, aged 79.

**Sherwood.**—On Jan. 3, at Manchester, William Dresser Sherwood, M.R.C.S.E., aged 65.

**Taylor.**—On Jan. 16, at Liverpool, Anne Elizabeth, wife of William Taylor, M.D., aged 56.

### A CASE OF DISLOCATION OF THE HEAD OF THE RIGHT FEMUR ON THE PUBIS OF THIRTY-NINE DAYS' DURATION REDUCED BY MANIPULATION. (a)

By HENRY GRAY CROLY, F.R.C.S.,

Senior Surgeon City of Dublin Hospital; Member of the Court of Surgical Examiners, Royal College of Surgeons.

A CASE of luxation of the head of the femur on the pubis having come under my care in the City of Dublin Hospital lately, I feel that the subject is of so much practical interest and importance that I consider it worthy of record and of being submitted to the meeting of this society. The following is a brief narrative :—

Darby O'Connor, æt. 40, a labourer, and native of the county of Clare, met with an accident in the following way on the 22nd of September of last year : he was leading a horse under a cart behind another cart ; that in front turned suddenly to the left, the heel of the cart striking the man with considerable violence on the upper and inner part of the right thigh, knocking him down. He suffered intense pain, and was carried home. The result of the injury proved to have been a dislocation of the head of the right femur on the pubis—an accident of much rarity. My friend and former pupil, Dr. Cullinan, Surgeon to the County Infirmary at Ennis, assisted by two local practitioners, endeavoured to reduce the luxation by means of the pulleys, the patient being under chloroform for three-quarters of an hour. It is right to mention that the poor man (who was evidently not aware of the serious nature of the accident he had met with) lay in bed, and did not seek admission to the infirmary for two weeks ; therefore Dr. Cullinan, so much time having been lost, laboured under great disadvantages, and did not feel justified in making further efforts at reduction, and wrote to me requesting me to admit the patient into the City of Dublin Hospital. The following was the appearance which this case presented on admission into the Hospital :—

The right thigh was *abducted*, slightly flexed, everted, *shortened half-an-inch*, and immovable ; the head of the femur was seen to be resting on the pubis, completely obliterating the natural fold of the groin ; the pulsations of the artery were felt at the inner side of the head of the bone ; the great trochanter was less prominent than on the sound side, and seemed to partly occupy the acetabulum.

Mr. Croly exhibited to the Society excellent photographs of the patient before and after reduction, showing the position of the affected limb and posture of the patient *resembling fracture of neck of femur.*

Owing to the rarity of the accident, and the length of time (nearly six weeks) which elapsed before the patient came to Dublin, the case excited much interest in the profession, and was seen by several hospital surgeons besides my colleagues Mr. Tufnell and Mr. Fitzgibbon, viz., Messrs. Porter, S. W. Wharton, Professor Hughes, Dr. Swan, Dr. Baxter, and others. It was the general opinion that much difficulty would be encountered in the effort to replace the head of the bone into the acetabulum, owing to the fixed position in which it remained for so many weeks. I determined in the first instance to break up adhesions, and then by manipulation to attempt reduction. Accordingly on the 11th of November, thirty-nine days after the occurrence of the accident, the patient was placed upon a mattress upon the floor of the operation theatre, in the presence of the hospital staff, visitors, and pupils, and brought under the influence of ether by Mr. Patton, the house-surgeon. The pelvis was firmly held by Messrs. Tufnell and Fitzgibbon, who assisted me. I flexed the leg on the thigh and the thigh as much on the abdomen as the rigid position would admit of. I grasped the ankle and knee, and rotated the limb perseveringly for more than half-an-hour. I felt and heard the crackling sounds produced by the yielding of the adhesions, occasionally abducting the thigh. When nearly an hour had elapsed the head of the bone slipped into the thyroid foramen, and on flexing the thigh again the head returned rapidly on the pubis. Having accomplished so much as to free the bone from the pubis and its surrounding adhesions, I was more hopeful of a successful result. I next rocked and rotated the thigh abducted, and brought the limb down, when I found that the deformity had disappeared, and with the satisfaction of finding that reduction was effected. The limb was then examined, at my request, by the several surgeons present, who were satisfied with the result. The legs were then bandaged firmly together, and the patient kept lying on his back, a catheter being passed as often as required. Considerable effusion into the joint followed the reduction. At the end of the third week the bandages were removed, and the man was allowed out of bed, and was soon able to walk about the ward.

---

(a) Read before the Surgical Society of Ireland. The discussion will be found at page 66.

This form of dislocation according to Sir A. Cooper's experience, occurs once in twenty cases of hip-joint dislocation, and may be confounded with fracture of the neck of the femur, in consequence of the posture of the limb. It may be useful and interesting to read the history of the dissection of an unreduced case of pubis luxation, from Sir A. Cooper's work, to further elucidate this most interesting case.

"The original acetabulum was partly filled by bone, *partly by the trochanter major*, and both were much altered in their form. The capsular ligament was extensively lacerated, and the ligamentum teres was torn through. The head of the thigh-bone had torn up Poupart's ligament so as to penetrate between it and the pubis. The head and neck of the bone were thrown into a position under the iliacus and psoasus muscles, the tendons of which, in passing to their insertion over the neck of the bone, were elevated by it and put on the stretch. *The crural nerve passed on the fore part of the neck of the bone upon the iliacus and psoas muscles.* The head and neck of the thigh-bone were much flattened and changed in form. Upon the pubis a new acetabulum had been formed for the neck of the thigh-bone; the head of the bone being above the level of the pubes, Poupart's ligament stretched across it on the fore part, whilst the femoral artery and vein were placed on its inner side, so that the head of the bone rested between the crural sheath and the anterior inferior spine of the ilium.

Malgaigne says neither shortening nor lengthening are real, but that the appearances depend partly upon the degree of abduction of thigh, but chiefly upon the oblique position of the pelvis, which in some cases is inclined upwards, and in some downwards, while in others it preserves its normal position without any obvious reason. *Retention of urine has been noted occasionally to accompany this dislocation.*

This dislocation forwards and upwards on the pubis (is called ilio-pubic by Nélaton and Malgaigne) is usually the result of forced extension of the thigh backwards upon the trunk, or of the trunk backwards upon the thigh. Thus, says Sir A. Cooper, it happens that a person, while walking, puts his foot into some unexpected hollow in the ground, and his body, being at the moment bent backwards, the head of the bone is thrown forwards upon the os pubis. The same effect may be also produced by a blow, or by violent pressure applied posteriorly, as when the wheel of a carriage passes over the posterior and upper part of the thigh. Forcible rotation outwards, combined with abduction of the limb is another, though less frequent, cause of this dislocation, and was evidently the cause in the case which I have just related.

The dangers of attempting the reduction of old cases are inflammetion of the hip-joint, fracture of neck of thigh-bone, and injuries to the knee (in pulley cases). *Fergusson never saw a successful case of hip-joint luxation reduced after three weeks*, and Sir A. Cooper limits the time for attempting reduction to eight weeks. Bryant says:—"When reduction by manipulation has failed, or is inapplicable, that by extension should be employed; and in the pubic form of dislocation *no other should be used* pulleys)."

Erichsen, at page 398, says:—"The attempt to reduce old dislocations of the hip-joint is necessarily attended with danger. In some cases the soft parts have been extensively lacerated; in others fatal inflammation of the joint has ensued; and in eleven cases with which I am acquainted the thigh-bone has been fractured. This accident has happened to surgeons of such eminence as Travers, Vincent, Malgaigne, Physic (of Philadelphia), Gwynn (of Brighton), Blackman (of Cincinnati), Harris, and Rodolph (of Pennsylvania Hosp.), to the surgeons of the North Hospital, in Liverpool, and to a practitioner in London now living. There is no proof that undue violence was used in any of these cases.

In my case the force was cautiously used, and I should say manipulation is much less dangerous than the pulley method. I find that M. Desprez, a French surgeon, in 1835, recommended manipulation; and in 1849 Fischer, of Cologne, published an account of a mode of reducing hip luxation by flexing the femur to an acute angle with the trunk, and impressing upon it gentle rotatory movement; and 1851 Dr. Reids paper on the subject was published in the *Buffalo Medical Journal*, also recommending manipulation by relaxing the abductor rotator muscles.

I consider reduction by manipulation the safest and best in all luxations, and this case which I have now brought under the Society's notice is a strong encouragement to adopt it.

◆

## SUCCESSFUL REMOVAL OF THE UTERUS AND ONE OVARY FOR THE RELIEF OF A SUB-PERITONEAL UTERINE TUMOUR. (a)

By WILLIAM THORNLEY STOKER, M.D.,
Fellow, Member of Council, and Professor of Anatomy of the Royal College of Surgeons in Ireland.
Surgeon to the Richmond, Whitworth, and Hardwicke Hospitals; Surgeon to Swift's Hospital for Lunatics; formerly Surgeon to the City of Dublin Hospital.

THE surgery of the abdominal and pelvic cavities has made such huge strides within the last few years, and engages the attention of our profession so closely, that I am glad to be able to offer the details of a case in which I have with complete success removed the uterus and one ovary, by means of an abdominal section, for the relief of a large uterine sub-peritoneal tumour.

It will be conceded that the treatment by surgical means of no other part of the human frame has undergone such a complete improvement and revolution of late as has that of the uterus and its appendages. It is but a few years since a host of diseases of these parts which were imperfectly understood—if understood at all—have been explored, explained, and illuminated; have had their pathology made clear, their causation defined, and their symptoms and treatment correctly laid down; have been, in fact, removed from the regions of obscurity and uncertainty, and placed in the realms of reasonable observation and intelligent treatment.

The class of cases in which the opening of the peritoneal cavity becomes a necessary step of surgical interference, has at this moment a surpassing interest, not merely because of the great issues involved on account of the importance of the organs we seek to remove or repair, but also because of the special bearing on intra-peritoneal operations which the great surgical problem of the day—that of antiseptic surgery, has. Even the momentous question of opening joints wanes in significance beside that of laying open the abdomen, for while one in many cases involves but the repair of deformity, or the salvation of the patient from a wasting and dangerous process, the other in all cases is an issue of life or death.

Although ovariotomy has become such a successful procedure, the operation of removing the uterus through the abdominal wall has not yet showed a large proportion of successful results, and has not, indeed, as yet been done with sufficient frequency to justify any statements as to what may in future be expected from it. The subject is one of such interest, that every operation, whatever its result may be, has a statistical value, even if it has no higher claim to attention ; and therefore it is without apology that I introduce the case of E. H., who is, as far as I could ascertain, the first person on whom hysterectomy through the abdominal wall has been successfully performed in Ireland.

---

(a) Read before the Surgical Society of Ireland.

She was a slender, sallow, dark-haired, but active looking person, above the middle height, æt. 26, and of rather a better class than the majority of hospital patients. She was admitted into the Richmond Hospital on the 31st of January, 1878.

She had borne one healthy, surviving child, six years before, but had not since been pregnant.

Two years previous to her admission, she noticed a tumour on the left side of her abdomen, which at that time gave her no inconvenience, but which two months later on began to increase in size and to produce some pain in the lower part of the abdomen when she walked. It did not, however, cause her any great inconvenience, or interfere with her general health to any marked extent. She menstruated regularly, but during the early stages of her disease each catamenial period had lasted from four to seven days.

She had sought advice at another hospital during the year previous to that in which I first saw her. I believe she was there examined by a surgeon of eminence, who having explored the tumour with an aspirator, came to the conclusion that it was solid, was probably a uterine fibroid, and not considering her at the time in a suitable condition, postponed operative treatment.

At the time she came under my notice her general health was fairly good, her menstruation was regular both as regards interval and duration, and was free from pain. The tumour caused her little inconvenience, and permitted her to take moderate exercise. The growth was easily perceived, causing considerable protrusion of the anterior abdominal wall, and lying chiefly to the left side. It was tolerably firm to the touch, giving a doubtful sensation of fluctuation, both to the finger and when percussed—so doubtful as to be of little or no value in guiding me as to whether I had a solid mass to deal with, or fluid contained in a tense thick-walled cyst. How deceptive this feeling was may be judged by the fact that during the operation subsequently undertaken, and even when the division of the abdominal wall had been completed and the surface of the growth laid bare to the finger, it was still difficult, nay impossible, to say whether it was solid or fluid, and it was only when an attempt was made to push a trochar into it that its solidity was demonstrated. An examination of the disease later on, showed that its extreme sponginess and elasticity conspired to produce this deceptive condition.

It seemed to be a smooth rounded mass, with a small protuberance attached to its upper and anterior surface, which could be readily felt and rolled from side to side by pressure, and which from its freedom of movement had apparently a narrow connection with the rest of the tumour. The introduction of a sound showed the uterine cavity to be of a normal size ; and it was peculiar that when the sound was *in situ*, with its handle projecting from the vagina, the point of the instrument was turned to the right when the large posterior mass was pushed to that side, and to the left when the small anterior offset was pushed to the right. This was explained after removal, by finding that the attachment of the small secondary tumour to the great one was such that it produced a revolution of the larger one towards the side opposite to that to which itself was pushed.

This feature of the antagonistic mobility of the two parts of the growth, is one of which I can find no record of a similar condition in any reported case of uterine tumour.

When the left index finger was introduced into the rectum, and the sound placed in the uterus with its point turned backwards, the posterior wall of the womb could be explored, and appeared to be of normal development and character. This has since been explained by finding that the cervix and the posterior part of the uterus adjoining it, were about as large as in the healthy state ; the fundus and front of the meridional zone being the seat of the tumour, and the cervix with its zone forming a sort of pedicle. The vagina was not elongated. The circumference of the abdomen at its greatest girth, a little above the cristæ ilii, was 27 inches. The pelvic cavity when examined by the finger through the rectum and vagina was free from any unusual presence, and of normal capacity. There was no interference with either urination or defæcation.

During her residence in hospital the tumour continued at first slowly, but afterwards rapidly, to increase in size, the globular effect, of which I have made mention, being especially active in its growth, and having at the time of operation a bulk almost as great as the head of a nine months' fœtus. When last measured, on June 5th, the girth of the abdomen had increased 9 inches, since her admission, and measured 36 inches. At this time a very small amount of ascitic fluid had found its way into the peritoneum.

It will be seen that the case was one presenting many difficulties of diagnosis. It was plain that we had to deal with either a uterine or ovarian tumour, but the numerous contradictory evidences which were present caused great doubt as to the exact state of affairs. On the side of ovarian disease was the freedom of the pelvic cavity, the ability to pass urine, the rapid increase in the volume of the mass, the normal size of the uterine cavity, the commencement of the tumour on one side, the youth of the patient, the apparent ability to discover a normal uterus by a rectal examination, and the doubt as to fluctuation being present. On the other hand, arguing for the uterine origin of the disease, we had this very doubt as to fluctuation—which cut both ways—the regular menstruation, the little alteration in the consistence of the growth, the comparative good health of the patient, and the rotation of the sound when the tumour was moved.

My final conclusion was that the origin of the disease was probably uterine, and was somewhat uncertain, but that be it a tumour of the womb, or an ovarian cyst, be it either solid or fluid, its removal had better be attempted, because the rapid growth it had lately undertaken threatened a speedy breakdown in the patient' health, and an ultimate sacrifice of her life. She had now been four months in hospital, and during the last of these the tumour had taken on very rapid increase, the ascitic fluid I have spoken of had made its appearance, and the woman was visibly commencing to decline in health. She now presented the appearance, when dressed, of a person in advanced and large pregnancy, and had got the sunken hectic look that one sees in a consumptive mother about to bear the child whose birth is to be the presage of her own death.

I fully explained the risk of the operation, and the uncertainty as to the nature of her disease to her, and got her permission to operate,—nay more, she was most anxious for an operation, and this in spite of extreme pressure which her friends put on her to decline it. I think she was the best patient I ever saw : from the time she entered the hospital until she left it, during six weary months, at least two of them passed in great suffering, her high courage never failed, her hope never wavered, her trust never shook. No one ever heard her utter a complaint. She came to hospital to be operated on ; she was determined to be operated on, and having been operated on, she was determined to live if she could. I cannot pay too high a tribute to her disposition, and to it in some measure I think her ultimate recovery was due.

The operation, which proved one of the most extreme difficulty, was undertaken on June 6th, 1878, three days after menstruation, and lasted nearly two hours, ether being the anæsthetic used. A thymol spray was produced by Professor Bennett, but the result was not an antiseptic one, for although the dressings were subsequently removed under spray, pus soon showed itself, and the procedure was discontinued.

I first made an incision several inches long in the linea alba below the umbilicus, and exposed the front of the tumour in the usual way, finding much difficulty in peeling off the omentum, which was very adherent. This was a long and troublesome process, necessitating the application of three catgut ligatures to various parts of the torn epiplöon. Having freed the tumour as far as the introduction of the finger into the wound would allow, I endeavoured, as its fluidity was still a matter of doubt, to pass the trochar into it, but found that it was solid and very elastic and resisting. It was now clearly ascertained to be of uterine origin. It was then necessary to enlarge the external wound, which I had to do to such an extent before there was room to extract the tumour, that it reached from near the ensiform cartilage to the neighbourhood of the pubis. After a good deal of manipulation and tearing through of extensive adhesions which existed on all sides, but particularly in front, where the omentum gave great trouble, the growth was drawn out, and a pedicle which the cervix uteri formed for it was ligatured with stout plaited silk. The ligature was applied by passing it twice round the pedicle and tying it tightly, the ends being cut short, and the tumour then removed by an incision through the substance of the uterus, half an inch beyond the point of deligation. It was now found that owing to its elasticity and vascularity the pedicle could not be tied with sufficient tightness to prevent the risk of subsequent hæmorrhage, so I transfixed it with a strong pin, which was placed externally athwart the wound, so as to secure the stump in view in case bleeding occurred, and another ligature was placed around the pedicle at the point of transfixion, and its ends twisted round the pin. The right ovary was removed with the tumour, but the left not presenting itself, was left behind, as it was deemed inexpedient to prolong the operation, the patient being apparently at the point of death from exhaustion, much blood having been lost. Two tags of bleeding omentum were ligatured and cut short, the peritoneum was rapidly sponged out, a glass drainage tube, 4 inches long, was secured in the lower angle of the incision so as to reach into the pelvis, and the abdominal opening was closed by points of interrupted catgut suture. The usual dressing of Lister was applied, the woman placed in bed, and a reaction from her collapsed condition brought about by the use of warmth and diffusible stimulants. It will be seen that five ligatures of strong carbolised catgut which had been applied to various bleeding points were enclosed in the cavity of the abdomen, while one of strong silk surrounded the portion of the pedicle concealed in the wound deeper than the transfixing pin.

Being loyal to antiseptic surgery, and as this case did not yield an antiseptic result, I should state that I do not claim to have successfully carried out Lister's method, first, because I used thymol, in which I have now no faith, instead of carbolic acid; secondly, because during a brief period of the operation the spray was discontinued, owing to some derangement of the engine; and lastly, because means were not taken to antisepticise the vagina, a proceeding which reflection will show is necessary in cases where the uterine cavity has been divided, as otherwise it may form a ready channel for the admission of septic matter to the wound.

I need not detail the daily history of the case subsequent to the period of operation, its progress was gradual, critical, and for the first ten or twelve days interrupted by many untoward symptoms. No sooner had reaction from collapse taken place than vomiting set in, and continued obstinately for eight days, after which time it subsided. It was combated by the use of various sedatives, and obliged us to have recourse to nutritive enemata to support the patient's strength.

A very troublesome and painful aphthous ulceration of the mouth and fauces appeared on the third day and per[illegible] until the eighth, when it also mended.

On the sixth day, great irritability of the vagina was experienced, accompanied by a fœtid discharge from that passage. This lasted for eight or nine days, and was much relieved by injections of diluted Condy's fluid.

Both pain and want of sleep demanded the frequent use of hypodermic injections of morphia for the first fortnight following the operation.

Her dietary was a matter of much difficulty owing to the intense gastric irritability which was present, and exercised our culinary knowledge to the fullest extent; indeed, I think that she would have died but for the support afforded by nutritive enemata. The stimulant which agreed best with her was champagne.

A catheter was introduced at regular intervals during the first five days, after which time she passed water easily without assistance.

The bowels acted naturally on the 10th of June, four days after the operation, and continued to do so up to the time of her convalescence, requiring to be occasionally checked by the use of an enema of starch and opium. This was due to the irritability of the lower bowel produced by the frequent use of nutritious injections.

The dressings were removed on the second day, being saturated by an abundant and very offensive discharge. The upper portion of the wound was now found to be almost healed, while through the drainage tube in the lower angle and from the neighbouring corner of the incision, flowed a dark and fœtid pus. The dressings were renewed every second day from this until the termination of the treatment. The tube was withdrawn five days subsequent to the operation, and the channel where it had been, gradually closed as the quantity of discharge diminished.

On the eleventh day the pin with the slough of the pedicle separated, and the deeper portion of the uterine stump with the more remote and earlier applied ligature receded gradually, leaving a thimble-shaped cavity which was plugged with lint daily, and which contracted by degrees, being, at the time she left hospital, barely large enough to admit a small probe. I may despatch all further mention of this sinus by stating that it remained open, and gave exit to a very slight discharge, for about twelve months, when the deep ligature which had surrounded the pedicle was extruded through it, after which the opening completely healed.

The temperatures of the case present no feature of note. They were low, averaging from 99° to 101°, the highest point attained being on the fifth day, when the thermometers in the axilla registered 102·2°. On the twentieth day the normal temperature was regained, and the convalescence which may then be looked upon as having commenced, went rapidly and favourably on.

The woman left hospital on August 1st, about seven weeks after operation, in excellent health, and gaining quickly in condition.

An examination of the diseased part after removal, showed it to be a large myoma, occupying the upper and anterior wall of the uterus, and leaving the cavity of that organ, the posterior wall, the cervix and cervical zone in their normal condition. The small tumour which had been felt during previous examinations, was a secondary growth from the left and upper portion of the anterior surface of the main tumour, and its freedom of movement was now accounted for by the tenuity its attachment was found to have. The tumour was encapsuled in the usual way by the muscular substance of the uterus, and could, in many places, be separated by a little tearing from its attachments, but over most of its surface the connections were so strong as to show that in this case, at all events, the procedure which has been proposed of disencapsuling uterine sub-peritoneal fibroids through an abdominal incision, would have been impossible. Although very tough, and resisting violence to a marked degree, it was spongy and elastic, conditions which accounted for the deceptive feeling of fluctuation it had possessed when *in situ*.

The entire mass measured—

Vertically, 11 inches; transversely, 10½ inches; antero-posteriorly, 5½ inches; in horizontal circumference 26¼ inches; in vertical circumference, 26 inches; and weighed 14 pounds.

I saw and examined the subject of this memoir in consultation with my colleague, Mr. Thomson, on the 3rd of December just gone by. She has remained in excellent and vigorous health, her spirits are good, she has grown plump and ruddy, and can discharge her household work as well as at any time of her life. Having one ovary remaining she is conscious of a slight monthly sensation of menstruation, and from June to September inclusive, of 1879, she menstruated slightly, the discharge being scanty, lasting for one day on the first occasion, and for three days on the subsequent ones. Since September it has not appeared. It came evidently from the cervical canal and whatever remains of the neighbouring cavity.

Her bowels and bladder act naturally and without trouble. The vagina is as pliant, healthy, and free from contraction or adhesion as it would be in a woman who had not undergone operation. To both the finger and speculum the os uteri and cervix present the characters you would expect in a healthy woman who had borne one or two children. The sound could be passed for about three-quarters of an inch into the cervical canal, and in the normal direction.

Apart from the interest this case possesses in having a successful issue out of a disease which but a few years back was regarded as beyond the powers of the surgeon, and of which a skilful and enterprising gynæcologist, when writing on uterine fibroids nine years ago, said—"Of these the extra-uterine or sub-peritoneal being entirely beyond the reach of treatment, must be dismissed after a brief notice"—apart from this, I say, and independent of some other points of interest which will have suggested themselves to those conversant with uterine diseases, this case offers one or two matters for reflection.

I think it affords very substantial testimony to the value of the drainage tube, for with every knowledge of the accommodating power of the peritoneal surface, and its capacity for ready absorption, I cannot believe that the large amount of offensive discharge which was voided could have been absorbed, or even that a considerable part of it could have been taken up, without doing fatal mischief. In my opinion the patient would have died but for the ready exit afforded by the tube to poisonous matters. In speaking of the drainage tube I would call attention to the fact that it is not necessary to leave it *in situ* for a very long time, because after its removal a sinus remains, which only closes as the discharge diminishes. It is then, I think, only necessary or advisable to leave it in for sufficient time to establish this channel, for it will be readily conceded that while it serves an excellent purpose, the tube itself may be a cause of irritation, and should be dispensed with as soon as possible. In this instance I removed it on the fifth day, and in future I am disposed to do so at an earlier moment.

The question of the propriety of leaving one or both ovaries behind when the uterus has been removed, is one about which much difference of opinion may arise. It may be argued that the monthly discharge of the contents of one or more Graafian vesicles into the peritoneal cavity is an undesirable circumstance, and might be the cause of subsequent mischief. For my own part I do not see how this could be the case. The rupture of the peritoneal covering of the ovary at the point of discharge is not more likely to cause irritation than it would be in the case of a healthy woman who had never been the subject of operation, and in whom the peritoneum is infinitely more tender and susceptible than in a person in whom its cavity has been laid open for disease; besides, the size of the discharged ovum—1-120th of an inch—and the minute quantity of fluid which accompanies it, forbids serious apprehension from its presence in the peritoneal sac.

On the other hand I consider that, provided the ovaries be healthy, a distinct advantage must obtain from their being left *in situ*. A female possessed of these organs would, accidental circumstances being set aside, enjoy better health and spirits than one in whom they were wanting, just as a male possessed of testicles is more active, vigorous, and intellectual than one who has lost these appendages, or in whom they are diseased, or wanting from arrest of development.

In the case I have recorded the ovary was left behind more from accident, from the haste demanded in the completion of the operation, than from deliberate design; but in any future case in which I may have to remove the uterus it is my present intention to leave one or both ovaries behind, provided I find them healthy.

Bearing on this question I may mention a case of M. Schwartz, recorded in the *Archiv. für Gynäkologie*, and referred to in the *Brit. Med. Journal* of the 10th of Jan., 1880, in which a midwife violently tore away during labour the whole of the uterus under the impression that it was the after-birth. The ovaries and Fallopian tubes remained in the abdomen. The woman recovered in fifteen days, and has since enjoyed good health. Venereal disease continued to exist, although less pronounced than formerly.

I cannot finish my memoir without recording my thanks to my colleagues for the assistance they afforded me in this very difficult case, and particularly I would express my gratitude to Dr. Kidd for the advantage accorded to me by his experience and help. Of Mr. Butt also, the pupil who took charge of the case, and to whose devotion the woman in a large measure owes her life, I cannot speak too highly. With a full knowledge of the generous attention often accorded by students to the cases under their care, I have never seen such untiring attention, and so complete a sacrifice of self, as was offered by this gentleman in this instance.

## ROYAL INFIRMARY, MANCHESTER.

### *Two Cases of Penetrating Wound of Knee-joint.*

Under the care of Mr. HEATH.

Reported by Mr. JOHN SUTCLIFFE, M.R.C.S.,
House Surgeon.

JAMES M., æt. 24, a strong healthy-looking young man, was admitted into this hospital on September 11, 1879, having sustained an injury to his knee by a bar of iron falling upon it. On examination, it was found he had a compound fracture of the left patella. The bone was broken transversely across its middle; the external wound was two inches and a half long, the outer end being a little to the inner side of the middle line. There was escape of synovial fluid. The finger could be passed between the fragments of the patella into the interior of the joint. Under the spray the joint was syringed out with a solution of carbolic acid, 1 in 20, and dressed according to Lister's method. The limb was put up in a back splint, with a foot-piece, and two side splints. No sutures were applied, nor was any drainage used. An ice-bag was placed over the dressings, and kept there for fifteen days. The wound was dressed next day, and every alternate day afterwards, until Oct. 5th, from which date it was considered to be only necessary to dress it twice in each week. The temperature during the first week on two occasions, in the evenings, reached 100·4° F., after which it fell to, and remained about, normal.

On Oct. 17th, the wound was completely healed. A starch-bandage was applied, and he was sent to the Convalescent Hospital at Cheadle, on Nov. 8th.

He returned to the hospital on Dec. 16th, "to show himself," when the patella was found to be firmly united and the knee-joint pretty freely movable. He was ordered to wear a back splint. During the progress of the case the organisation of the blood clot was beautifully seen; there was a slight discharge of sero-sanguineous fluid, but no pus.

John M., æt. 40, a joiner, came to the accident room at this hospital, on Sept. 12th, at 6 p.m., having accidentally wounded his knee with the sharp point of an axe. On examination, the wound was found to be about one inch in length, and situated above and somewhat to the inner side of the right patella. There was escape of synovia, and the finger could be passed above the upper margin of the patella into the knee-joint. He refused to be made an in-patient, so the wound was dressed with glycerine and carbolic, and he was taken home.

At 10 p.m. he returned, desiring to be admitted.

Shortly afterwards the joint was syringed out with the carbolic solution, 1 in 20, under the spray; the mode of dressing was Lister's, and the whole limb was put up in a back splint, with foot-piece and two side splints. An ice-bag was kept over the knee until the 26th.

Until the 30th, the wound was dressed every other day, but afterwards only twice in each week. The temperature gradually rose to 101·4° F. on the evening of the 15th, after which it fell to slightly below normal, about which point it remained.

On Oct. 14th the wound was perfectly healed, and on the 21st he was discharged, with all the movements of the joint as perfect as they were before the accident.

# Department of Lunacy.

## PRIVATE LUNATIC ASYLUMS.

We draw attention to Dr. Bucknill's paper on Private Lunatic Asylums read at a recent meeting of the South London District Metropolitan Counties Branch of the British Medical Association, because it bears hardly, and in many respects unfairly, on the privileges and character of the keepers of the establishments condemned with a wholesale censure it is impossible to endorse. The principle on which Dr. Bucknill proceeded was an evident antagonism to private asylums; and in his objections he showed himself animated by a spirit of hostility that permitted no recognition of anything save the most evil consequences as following from the existence of those institutions. Declaring that he was unwilling to attack any individual, he sought to argue the point from a broad basis of inexpediency, urging that the retention of diseased and helpless persons in private houses is calculated to favour abuses which have for their end the pecuniary gain of the proprietors. The question thus proposed is a fair one for discussion: but the method of considering it should be rather unbiassed and argumentative, than heated by the incorporation of animus, however well-founded it may be. And we venture to think that, unconsciously, perhaps, Dr. Bucknill has, in this instance, been led away by apparent facts, which a little further reflection and investigation would have convinced him, are unfounded and fallacious. He places so little reliance on the provisions made for preventing the improper incarceration of sane people, and has been so far sympathetically led away by the popular cry of injustice, that he somewhat ungenerously hints at practices which we have every assurance are as rare as they would be, were there nothing but public asylums in the land. As Dr. Bodington very temperately observed in the discussion on Dr. Bucknill's paper, that gentleman had been unduly lavish in his ascription of the worst character to the keepers of private asylums. That there are *some* dishonourable medical men is unfortunately true; but that the number is more than a very small part of the whole profession, is as true; the injustice, therefore, of characterising the class from the evidence of wrong-doing in a very minute section of it, is both misleading and disingenuous.

We unhesitatingly condemn such ill-considered remarks as those to which Dr. Bucknill committed himself. Either he is ignorant of the provisions made to secure the safety and well-being of private insane patients; or he is unwilling to admit their adequacy to meet the peculiar conditions under which they are retained. In either case he should put himself in a better position to act as judge in the matter, ere he descends to the sweeping denunciations he has been guilty of. At the present time the inspection of private houses and the stringent rules by which the Government regulations require them to be conducted, are sufficient protection to those within them; while, moreover, they effectually guard against any miscarriage of justice, such as that familiarised to the readers of sensational novels of the present day, or those older romances of the type exemplified in "Hard Cash."

Those who, like Dr. Bucknill, are anxious for improvement in the lunacy laws, will not attain the end they have in view by declamatory outcry against private asylums. The imagined evils they depict, in connection with these, are day by day refuted by the experiences of the Visitors who are appointed to report on their condition, and on the condition of the patients therein. So long as the Government officials are enabled to satisfy themselves that the gross misusage attributed to the proprietors of private asylums have no real existence, but that the institutions they control are—as they undoubtedly prove to be—exerting a beneficial influence and a healthy curative action on their inmates; then so long the outcry raised against them will be productive of nothing beyond a temporary excitement, of possible use, it may be, in drawing attention to the real excellence of the system at present in use.

Into the question of administration of the Lunacy Laws we do not now propose to follow Dr. Bucknill. His schemes are illusory and ill-considered, and can hardly be treated with the gravity that would be accorded to a well-matured plan. We have been anxious, in this place, to protest against the ill-advised course he has pursued in his strong outcry against a useful and well-conducted institution. We would advise his making himself actually acquainted with the working of some private asylums ere he ventures again to denounce them in the manner he did last week. He will find much to interest, much to instruct; and, as a rule, he will find their owners courteous gentlemen, and not the dishonourable exponents of the *auri sacra fames* his fancy has portrayed.

In the principal large towns of the United Kingdom the annual rates of mortality per 1,000 last week were—Brighton 16, Bristol 17, Leeds 17, Leicester 18, Edinburgh 18, Portsmouth 19, Bradford 20, Oldham 23, Norwich 23, Salford 24, Wolverhampton 24, Glasgow 24, London 25, Nottingham 25, Birmingham 25, Sunderland 26, Newcastle-upon-Tyne 27, Plymouth 27, Hull 27, Manchester 28, Liverpool 28, and Dublin 38.

# Transactions of Societies.

## CLINICAL SOCIETY OF LONDON.

The last meeting of the Clinical Society of London was held on Friday evening, Jan. 23rd, when the President, Dr. E. H. Greenhow, delivered a short address.

Mr. Pick on

### A CASE OF SUB-ASTRAGALOID DISLOCATION, IN WHICH REDUCTION HAD BEEN EFFECTED BY A SOMEWHAT NOVEL METHOD, AND A SATISFACTORY RESULT OBTAINED.

The case was one of ordinary sub-astragaloid dislocation, where the whole of the tarsal bones, with the exception of the astragalus, were displaced outwards from this bone, which remained *in situ*, in contact with the tibia and fibula. All the ordinary methods, by manipulation pressure, extension and rotation, were tried, after division of the tendo Achillis, without success, and in consultation it was determined to make one more attempt at reduction, and failing this, to perform excision of the astragalus, as the foot would clearly be of no use to the patient as it was, and the skin over the prominent head of the bone threatened shortly to give way. At Mr. Henry Lee's suggestion, the following plan was adopted. The middle of a bandage was twisted in a clove-hitch and passed round the foot just behind the heads of the metatarsal bones: the two ends of the bandage were then tied and passed over the operator's shoulders, the knee of the surgeon, at the same time, being placed in front of the lower extremity of the tibia. Considerable extension in a direction forwards was then made, and the foot, at the same time, moved from side to side, as far as the amount of tension would allow. After about a quarter of a minute's extension in this way, the bones quietly slipped into their places. The patient made an uninterrupted recovery. Mr. Pick stated that he believed the difficulty in reduction in this case was due to the posterior inferior margin of the astragalus being wedged in the interosseous groove, between the articular facets, on the upper surface of the os calcis, and at the same time the constricted neck of the astragalus locked by the sharp posterior margin of the scaphoid bone. It was taking this view of the case which induced Mr. Henry Lee to propose the plan of attempting reduction by making extension directly *forwards*, so as to unlock the bones and cause the head of the astragalus to recede into the cup-shaped posterior surface of the scaphoid.

Mr. Bryant said that some time ago he had a case under his care which he considered one of sub-astragaloid dislocation. He carefully studied the foot, in connection with it, and was led to the same conclusions as had occurred to Mr. Pick. He thought, too little attention was paid as a rule to the possibility of such cases being called dislocations of the astragalus. The method of reduction employed he considered sufficiently ingenious, and to be worthy of imitation. He regretted that no drawing had been made of the everted foot, the degree of outward displacement having been apparently extreme.

Mr. Henry Lee could not add much to Mr. Pick's description. Some points, however, might be dwelt on somewhat more fully; and the importance of careful consideration of it in connection with any similar case, could not be too much insisted on, since amputation is often too readily assumed to be the only available means at hand, of treating this injury. Mr. Lee referred to a case under the care of the late Mr. Hancock, in which only parallel extension had been resorted to, and pointed out the necessity of *forward* extension at the same time, the bandage being applied along the inner side of the scaphoid bone.

Mr. Jas. E. Adams said the museum of the London Hospital contained a typical dried specimen, in which the foot being turned in the astragalus was dislocated outwards.

Dr. Hewan read a paper on

### A CASE OF GUNSHOT WOUND,

for Mr. E. Adams.

In 1862 A. B., ship's carpenter, aged about 37 years, a tall, stout man, of temperate habits, was shot by a ship's captain in a row on board a palm-oil trading ship, at anchor in a river on the west coast of Africa. The bullet was fired from a large Colt's revolver at a distance of about five yards, at 10 p.m. Immediately the report was heard the carpenter gave a loud shriek, clasped his hands over his breast, and rushed across the deck into the forecastle, exclaiming, "I'm shot; fetch the doctor."

I was standing close to the captain at the moment of the occurrence, and instantly followed the wounded man. He was lying on the floor of the forecastle deck, and as soon as he saw me said he was done for, and felt in a dying state. Collapse came on rapidly, although there was little or almost no external hæmorrhage. I made an examination of the chest, and found the entrance wound of bullet above the left nipple, between the third and fourth ribs.

A bed was prepared on the main deck, and to this he was removed as soon as he had taken a dose of brandy and laudanum. The surgeon of a neighbouring vessel had meantime been sent for, and on his arrival I made a careful search for the bullet. It was found on the inner edge of the scapula, at a point opposite to, but on a somewhat lower level than the point of entrance, projecting under the skin of the back, which was extremely thick. There was a large patch of emphysema all round it extending up to the level of the shoulder-joint, and towards the spine. As we turned the patient over, he began to cough, and brought up a large quantity of blood, clear and frothy, evidently from a pulmonary vessel.

It was decided to remove the bullet, and this was done by means of a tolerably long incision, sufficient to admit two fingers. The operation was performed rapidly and with little difficulty. A conical ball of lead, *grooved* at the tip, as if it had struck a hard substance in its passage, was extracted.

The operation wound was treated as a simple incised one, with one suture and adhesive strapping. The wound of entrance was covered with cold water dressing. There was grave collapse, but the patient was well watched, and *encouraged by the constant presence of the doctor*.

During the first twenty-four hours brandy (with laudanum) was given pretty freely, but after this time very sparingly. The laudanum was continued for a week or ten days. It appeared to answer admirably, soothing the patient into a state of happy indifference and freedom from pain and anxiety. The blood from the lungs gradually diminished; there was scarcely any direct pain after the first day or two, and at the end of a fortnight the patient was in a condition of absolute safety. It should be noted that he was well fed with soup and mutton tea, and was allowed to drink lots of cold water. At the end of about six weeks he was transferred to a homeward-bound ship, and arrived safe and well in Liverpool. I heard of him three years later as being alive, well, and able to make long sea voyages as well as any man.

I offer no comment on this case further than to say that the treatment was the best that could be adopted under the circumstances. It was very rough, very unscientific, *very successful*.

Dr. C. T. Williams was surprised that no injury was done to the heart, &c., in wounds of this kind; and he considered the case read by Dr. Hewan to be even more remarkable than that related by himself a short time since to the Society.

Dr. F. Robinson said that many similar cases to this occurred during the progress of the Crimean War. He remembered one, that of a lieutenant, who was shot through the lung, and who with rest and dietetic precautions, recovered and returned to England, where he ultimately died from diarrhœa, contracted by unduly indulging in fruit.

Mr. Henry Lee considered that the treatment denominated rough in the paper, was mild compared with the usage of former days. He thought it not impossible to employ antiseptic precautions in treating this class of wounds.

Mr. R. W. Parker remarked that there were several cases during the Franco-German war of this kind of injury, and several recovered. He believed the rapidity with which the bullet entered the body, producing an incised rather than a contused wound, was one chief reason why the cases often terminated favourably.

Dr. Mahomed related the history of a case in St. Mary's Hospital. It was that of a man with a bullet wound in the lung, complicated by pleuritic mischief, the membrane being seemingly filled out with blood. The patient being subject to rigors, tapping the chest was discussed. The man, however, ultimately recovered; and he (Dr. Mahomed) thought rest, without operative interference, in similar cases, will effect cure.

Dr. Robinson did not remember any instance of tapping in these cases.

Dr. Hewan, in reply, corrected the impression under which several speakers laboured, that the injury occurred on the open sea. The ship was at anchor in a malarious district off the coast of Africa. He ascribed the successful result to the good treatment the case received.

DR. S. O. HABERSHON on

### A CASE OF PYELITIS—DISCHARGE OF PUS—INCISION IN THE LOINS—RECOVERY.

A. P., æt. 28, was admitted into Guy's Hospital under Dr. Habershon's care January 29, 1879. He was a delicate looking man, by trade a carman; his mother and four brothers were stated to have died from phthisis. Four months before admission he first noticed blood in his urine, and he then experienced pain at the end of the penis during micturition. For some time previously he had had pain in the left arm, left side, and thigh, extending down the inner part of the limb to the knee. The blood passed was mixed with the urine, and gave to it the appearance of light red port wine. He did not pass any clots. About a month after passing blood he noticed a swelling in his left loin, which increased in size till it reached the size of a goose's egg. The severity of the pain compelled him to remain in bed; he stated that one night the swelling burst, it suddenly disappeared, and that he then passed about half-a-pint of pus with his urine, and continued passing a little pus at the end of micturition for three or four weeks. The urine was of a yellowish colour. During the formation of the swelling the bowels were confined for a fortnight, but afterwards diarrhœa came on. On admission the patient appeared ill and distressed, his sleep was disturbed, he rested on his back, but movement gave pain; there was occasional nausea, the tongue was red and dry, the bowels regular, the abdomen was rigid, especially on the left side, and he complained of pain when the slightest pressure was made on the left loin. There was dulness on percussion in the left lumbar region from the eighth rib to the crest of the ilium, but the dulness did not reach to the middle line. There was also fulness at the part, but no defined tumour could be made out. The voice was weak, respiration harsh at the right apex, no dulness at the apices of the lungs, but there was dulness at the left base, and there was absence there of breath sounds; respiration thirty-six per minute, the pulse was increased in frequency and feeble, the urine was clear, sp. gr. 1022, and free from pus, blood, albumen, sugar, phosphates; it contained a few squamous epithelial casts. The evening temperature was 102 deg. Morphia was given to relieve the pain. It was thought desirable from the distressed and feverish state of the patient to relieve the lumbar swelling; it was believed to be disease of the pelvis of the left kidney, and was thought to be strumous disease setting up suppuration, but it was doubtful whether there had been tubercular disease at the commencement, and the symptoms did not indicate calculus. On February 8th a fine trochar and canula were introduced into the swelling through the left loin, about midway between the ribs and the crest of the ilium, six ounces of a clear light green fluid were drawn off, and these were followed by about two ounces of pus. There was a fœtid smell; the fluid was of sp. gr. 1025, when boiled it became nearly solid, but it contained no urea nor uric acid, no hydatid, but pus cells and fibrin. On the 10th there was a good deal of perspiration. The dulness was less extensive, and there was less febrile excitement. On the 14th February the temperature was high, the abdomen flaccid, the tumour was distinctly felt. Mr. Davies-Colley made an incision under carbolic acid spray in the left loin, about three inches in length, just beyond the edge of the quadratus lumborum muscle; a firm, thick-walled, fluctuating tumour was found; and pus having escaped when a grooved needle was introduced, Mr. Colley made a larger opening, and nearly two pints of pus, mixed with a little blood, were discharged. The abscess extended beneath the ribs to about the eighth rib, and downwards about two inches below the crest of the ilium, forward to the edge of the rectus muscle; the walls of the sac were lined with calcareous material, but no calculus was felt. A tube eight inches in length was introduced, and the wound dressed with gauze in the antiseptic manner. The fluid gave a slight effervescence with the hypobromide solution, but no crystals of nitrate of urea could be obtained by nitric acid. Quinine medicine was continued. The improvement of the patient was uniform, the pain and perspirations ceased, and the discharge lessened. On the 27th three inches of the drainage tube were removed. At the base of the left lung there was still slight bronchophony, and prolonged expiratory murmur. On March 21st the patient was feverish, temperature 102°. The drainage tube had been removed, and the wound had healed. Mr. Colley again opened the wound and evacuated ℥ss. of pus. From that time he continued to improve. The discharge gradually lessened, but he remained in the hospital till May 15th. The sinus was still kept open, and he was directed to come to the hospital every third day to have the side dressed. The family history and the appearance of this patient suggested the probability of tubercular disease or caseous degeneration, and the discharge of blood directed attention to the kidneys. It was less easy to give a decided opinion as to the cause of the hæmorrhage. The absence of thoracic disease removed passive congestion from the causes of the complaint. There was no history of any blow or fall, and no proof of cancerous disease. The pain at the end of the penis and during micturition was indicative of vesical irritation as from a calculus, but these symptoms were only transient, and it was thought probable that if any portion of gravel had passed into the bladder, it had been quickly discharged. Two other modes of explanation suggested themselves to explain the hæmaturia and subsequent discharge of pus and enlargement of the kidney, for the swelling in the left loin was regarded (and correctly so) as a distended pelvis of the kidney; the one was that a calculus had blocked up the ureter, and had led to distension and suppuration in the pelvis of the kidney; and the other was that tubercular disease, or caseous inflammation of the gland, had been followed by chronic suppurative pyelitis.] The roughened semi-calcareous state of the diseased pelvis of the kidney when the finger was passed in through the incision showed that this latter supposition was probably correct, and no calculus could be felt. The patient was very ill on admission; he was feverish, and in constant pain and distress; there was hectic, and his strength was rapidly failing, and nothing could be more marked than the relief and almost daily improvement after the pre-evacuation had been made by Mr. Davies-Colley. If the operation had been postponed I have no doubt the man would soon have become exhausted, and the operation might, I believe, be more frequently resorted to in these case with benefit, and with the saving of life. It would be well if the whole gland could be safely removed, for it had become the mere cyst of a chronic abscess, and it formed a persistent source of irritation. From the large size of the abscess it may be doubted whether the suppuration was external to the gland; but it is well known that the pelvis of the kidney may attain to enormous proportions. Some years ago a man was under my care in the hospital who, from the age of sixteen or seventeen, suffered from periodic discharges of pus from the bladder, the discharge of pus being preceded by the formation of a large projecting sac extending from the ribs to the iliac fossa on the right side. It was found after death that a calculus blocked up the ureter on the right side, and that pus collected in the distended pelvis of the kidney, so as to reach several pints in quantity; when the distension became excessive there was a sudden discharge, and the swelling subsided. The distension of the ureter had become greater than the obstructing calculus, and the passage was then free. These attacks recurred, sometimes with intervals of several years, and the patient attained the age of sixty-four years. He died in Guy's from cancerous disease at the upper part of the remains of the kidney on that side.

DR. N. DAVIES-COLLEY.—I have but little to add to Dr. Habershon's report. The character of the abscess cavity seemed to me to indicate that it was formed by the dilated pelvis of the kidney. It consisted of a number of smooth-walled compartments freely communicating with each other, and partially separated by ridges, which were most of them encrusted with a calcareous deposit. With the exception of a short period during which pyrexia returned from the too early removal of the tube, the patient's progress to recovery was steady. He wore the tube for a month after he left the hospital, on May 15th. The discharge at first increased, probably from the discontinuance of the antiseptic treatment. It then gradually diminished, and finally ceased altogether at the end of October. His general health was good, but he had to be careful about his diet. Meat made him sick, so that he lived chiefly upon bread and milk. On November 5th, when I last saw him, the wound had been quite healed for two weeks, and there were no signs of any abdominal tumour, although I examined him carefully in the recumbent posture.

Mr. Golding Bird endorsed the opinion that the man's safety in this case was consequent on the action taken about it. The necessity for surgical interference was illustrated by a case he had seen for Mr. Durham, being that of a man with a swelling in the loin, but having also a bladder affection. It was a matter of uncertainty at first which indication to treat primarily. He decided, however, to cut down on the kidney, and when he explored it he found no stone, but some small concretions. The case did well after, and he felt that, the danger being so small, and an incision on to the kidneys involving no serious evil, in confirmation of diagnosis simply, it ought to be incurred.

Mr. Walsham drew attention to another means of diagnosing in these cases, viz., by introducing the whole hand into the rectum and exploring the ureter and pelvis of the kidney through the intestinal wall. This method, he said, was productive of no inconvenience to the patient, nor did it involve tearing the sphincter, or the occurrence of any injury.

Dr. Habershon had had no experience of this mode of diagnosis. The late Mr. Maunder had told him the sphincter is often torn in attempting to introduce the hand into the rectum. In the case he had read, however, no necessity for trying this method existed, since there was no doubt felt as to its nature. He thought it might be useful when, at an early stage of disease, difficulty of diagnosis was experienced.

### Dr. S. O. Habershon on

### A CASE OF CHYLOUS URINE AFTER AGUE IN INDIA—ALBUMINURIA—CESSATION OF CHYLOUS URINE, WITH THE DEVELOPMENT OF GLYCOSURIA AND POLYURIA.

Eliza M. C., æt. 59, was in India from the age of 2 years till she was 40, then after a stay of two years in England returned to India for ten years more; she had had twelve children, being married when she was about 15 years of age, and at 16 years of age she had her first attack of ague, and afterwards had repeated attacks before she left India. For three years she had noticed her urine to be white, like milk, and very thick. This condition continued till admission into Guy's Hospital on July 12th, 1876; her ankles and legs became swollen during the day. For three months her sight had failed and objects appeared misty. The patient appeared healthy, there was no evidence of disease of the lungs or heart, nor in the abdomen could anything abnormal be detected, except that the liver could be felt two inches below the ribs. The tongue was red and dry, the appetitite good; there was great thirst. The urine had sp. gr. of 1025, it was milky in appearance, and it contained both albumen and sugar; opium and quinine were given. On July 18th it was found that the urine which was passed before breakfast was lighter in colour, but that passed afterwards was opaque and milky; the quantity was nearly 5 pints. She was placed on the restricted diet for diabetic patients and gluten bread given. The urine remained milky, but the sugar lessened, and on July 28th and 31st was absent. On August 2nd the urine was still milky, and was described as in "lumps like jelly."

On August 7th the quantity of urine passed was 4 pints 12 ounces, but it was free from sugar. Various specimens of urine and of her blood were examined for filariæ, but none were found; when allowed ordinary diet the sugar returned. On August 23rd the urine passed before breakfast was quite clear and free from sugar, but it contained a small quantity of albumen, but that during the rest of the day was milky and became gelatinous on standing. On September 20th there was no sugar in the urine, its sp. gr. 1020, but the sugar returned after the allowance of ordinary bread. On October 10th Mr. Higgins found opacity of the lenses, and on the 17th performed iridectomy on the left eye. November 11th, the urine passed after breakfast became clear; 15th, it was clear, of sp. gr. 1012, free from albumen, but it contained sugar; about 4½ pints of urine were passed during the day. When the ordinary bread was allowed the sugar increased; and on November 23rd the sp. gr. was only 1010, but the urine still contained sugar. On December 2nd she passed 9 pints of urine in the twenty-four hours, clear and pale, sp. gr. 1010, free of albumen, but containing sugar. On the 19th 8½ pints of urine, sp. gr. 1014, contained 242 grains of sugar. On January 6th 10 pints of urine were passed of sp. gr. 1008, and a small quantity of sugar was present. The tincture of iron was prescribed, and afterwards ammonia with laudanum. During the whole of January the urine was about the same, clear, 8 to 10 pints in quantity, sp. gr. 1010 to 1012, and it contained sugar, and on January 27th there were 1800 grains of sugar found. On February 5th she passed 9 pints, sp. gr. 1010, and after fermentation the sp. gr. was 1006, and about 730 grains of sugar. She remained in the hospital till February 21st; her general health had improved, the chylous urine had ceased, the albumen had also disappeared, but the urine continued of low sp. gr., and it contained sugar. On February 17th it was 9 pints, of sp. gr. 1014. This case was one of chylous or of lymphous urine, for there was spontaneous coagulation, but it was associated with glycosuria. Albumen soon disappeared, but the sugar remained. At first the sugar ceased when the diet was restricted, but it afterwards became more decided and permanent. Search was made many times for filariæ, but none could be detected in the blood after careful microscopical examinations. In recorded cases of chylous urine, the condition has been referred to change in some of the lymphatic vessels connected with the kidney, but its association in this instance with glycosuria, suggested the idea that both conditions, the presence of chyle, and of sugar in the urine, might be referred to change in the liver. Of the hepatic disease there was no positive proof, and the connection with the liver must be regarded as conjectural, at any rate as regards the chylous state.

Dr. Pavy said that this same patient was subsequently under his care. During the time, however, no chyluria was observed, and he considered it a case of mild saccharine diabetes. The peculiarity of it arose from the association of diabetes mellitus with diabetes insipidus. He had once a similar case, that of a boy, under treatment, and in him he found that on non-restricted diet the large quantity of sugar excreted when the diet was checked, ceased to be passed with the urine. He was convinced the two conditions were a result of vaso-motor paralysis affecting the chylopoietic viscera, and interfering with the due transformations to which the blood within their vessels is submitted. He related a case, under his observation in 1875, of a lady, concerning whom he was consulted by a country practitioner. She showed chylurous symptoms, but becoming pregnant, she lost them when advanced into the third month of gestatien. After delivery, however, the chyluria returned. He concluded that this was due to some abnormal connection set up between the lacteals of the chylopoietic viscera, on the one hand, and those of the renal, on the other. The great inequality of the blood pressure on the two systems precluded the possibility of any natural connection.

### CUPRIC TEST PELLETS FOR SUGAR.

Dr. Pavy said that he desired to introduce to the notice of the Clinical Society a new form of test for sugar, which he thought would prove of no inconsiderable service to the medical practitioner. Of the various reagents that have been recommended for the detection of sugar, his experience led him to consider the cupric test by far the most reliable, and this view stood in accord with that which was generally entertained by analytical chemists. It had been hitherto the practice, certainly where delicacy and precision were in question, to employ the test in the form of a solution prepared by mixing an alkaline tartrate with sulphate of copper and either potash or soda. Such a solution contains the oxide of copper in a state ready to be reduced to the condition of the suboxide when in contact at a boiling temperature with glucose. When freshly prepared this solution fulfils all that can be desired, but there is the disadvantage belonging to it that, after being kept for some time, especially if exposed to light and air, it is liable without the presence of sugar to throw down a certain amount of reduced oxide on boiling, and thus possibly to mislead unless precautions are taken to provide against it. Besides this objection the liquid, unless frequently used, is very apt to cause the stopper of the bottle in which it is kept to become fixed. In fact it must be spoken of as an inconvenient liquid to keep for only occasional use. He had long felt that it would be very desirable if the ingredients of the test could be incorporated and kept in a solid form; and some years ago he had made a fruitless attempt to attain this object. Latterly he had given his attention afresh to the subject, and the test pellets before the Society were the result of the task undertaken. He need not enter into details regarding the ideas which failed on application to yield a satisfactory result. It would suffice for him to say that the test pellets contained the solid ingredients of the cupric test solution in a dry state, and that they were brought into the condition of a coherent mass by compression. The preparation had been placed in the hands of Mr. Cooper, of 26 Oxford Street, who, it was but justice to say, most successfully met the difficulties that were unexpectedly encountered. An article had been produced which met with Dr. Pavy's entire satisfaction, and which he felt was adapted hereafter to render good service in relation to diabetes. There appeared no reason why the pellets should not keep for an indefinite time without undergoing change if preserved in a closed bottle away from moisture. In using them all that was necessary was to place one in a test tube with about 3c.c., or rather under a drachm, of water, and to apply heat until complete solution had occurred, with the accomplishment of which a clear deep blue liquid would be formed which actually constituted the cupric test solution. At present it was only as a qualitative test that the pellets were introduced, but there was no reason that hereafter the preparation should not be conducted with sufficient attention to accuracy of weighing to render them applicable for quantitative analysis. Dr. Pavy furthered mentioned that the test pellets exhibited were ready to be sold by Mr. Cooper, chemist, of Oxford Street, in bottles containing twenty-four, at a cost of one shilling.

## SURGICAL SOCIETY OF IRELAND.

### SESSION OF 1879-80.

THE third meeting of the session was held on Friday evening, January 2, in the Albert Hall, Royal College of Surgeons, Dr. **Mapother**, President of the College, in the chair.

Mr. **Tufnell**, hon. sec., read the minutes of the previous meeting, which were signed.

### MULTILOCULAR OVARIAN CYST.

Dr. **Atthill**.—This is an ovarian cyst which I removed four days ago from a lady, æt. 42. The operation was insisted upon by herself, for the size of the tumour not being large, it was suggested that it might be postponed. However, at her urgent desire I operated. I was willing to do so mainly on the ground that she had had two attacks of peritonitis, and rapid emaciation was also manifest. The operation was easily performed, the tumour being exposed without difficulty. There were considerable anterior adhesions, but being of recent origin they were ruptured without much difficulty. From first to last she did not lose an ounce of blood. A remarkable point connected with the cyst is the extremely small pedicle, which seems to me to be the Fallopian tube only. The cyst is multilocular and purely ovarian, as distinguished from par-ovarian, which unilocular generally are. On this, the fourth day after the operation, her temperature was 99 deg., and her pulse only 90. In a clinical point of view the case is interesting, as showing the advantage of early operation.

Mr. **Henry Gray Croly** read a communication on a case of

### DISLOCATION OF FEMUR ON PUBIS,

which will be found on page 57.

Mr. **Tufnell** said the deformity was extremely well represented in the photograph, which he had recommended to be taken. One foot was turned perfectly at right angles to the other.

Dr. **Swan** saw the case under several conditions—before it was reduced, during the reduction, and immediately afterwards, and again about three weeks afterwards, when the man was walking about. It was rather a surgical curiosity—so are that Sir Astley Cooper had not given the details which he himself had seen of such a case, but had got them from a friend. Manipulation he regarded as the best method of operation in a case like the present, because, in the first place, the number of adhesions which are broken up in the manipulation must have seriously interfered with the application of pulleys, and, secondly, the method by which reduction occurred into the thyroid foramen and acetabulum would be borne out by the application of leverage to the bones. Thus, first, by the flexion of the femur on the abdomen, the head was tilted over the brim of the pelvis into the thyroid foramen; and then, it hit against the lower edge of the thyroid foramen, and tilted first into its unnatural position, and secondly into its natural bed, or the acetabulum.

Professor **Bennett** thought Mr. Croly's communication was of very great importance, because it demonstrated the fact that manipulation carried to its full extent will certainly succeed where the pulleys fail. Just before the case in question occurred he had had under observation a case of dislocation upon the pubis, but a recent one. The man whom it befell was admitted to hospital four hours after the injury; he had fallen off the gangway in the dark. In this case the attitude of the limb and the details otherwise were such that the pupils had made the diagnosis before he himself arrived. The patient having been put under ether to the full extent, the extension process was applied with two sheets, three strong men being placed to the counter-extension, and three to the extension, but although the man was slight, and seemed extremely weak, they produced no effect whatsoever upon the bone. He then resolved to abandon the extension method and try that which, doubtless through oversight, Mr. Croly omitted to name, viz., Bigelow's mode of reduction, carrying it out in detail. Flexing and carrying the limb to the opposite shoulder and sweeping it to the position of abduction, rotated outwards, the bone went in as if creating a fracture rather than the setting of a dislocation—with a grind rather than the snap ensuing on ordinary reduction. However, that was the only dislocation on the pubis he ever saw. He could not, therefore, speak with authority on the matter; but, so far as his particular case went, the manipulation conducted single-handed by himself had succeeded with ease, whereas the strain of six men first attempted had proved ineffectual. Mr. Croly was to be congratulated on his success, having regard to the date at which he operated, for had a week more elapsed he might have declined such interference.

Mr. **Wharton** said through the courtesy of Mr. Croly he had seen the case under discussion. Having arrived late last evening he did not know whether a case he had himself brought before the Society many years ago had been mentioned, namely, one illustrating his failure in the management of a dislocation of the femur. In that particular case he converted the dislocation of the bone on the dorsum ilii into a dislocation into the thyroid foramen. He concluded the mistake he had made was that he had not abducted the limb. Had he done so when the edge of the femur arrived at the outer part of the acetabulum, he would have reduced the dislocation at once. Although his object was not to put himself forward as the first to introduce into Dublin this particular method in the treatment of dislocation of the femur, yet after reading his communication here he received from Dr. Darby a letter that he had reduced a dislocation of the femur on the dorsum, the result of a fall from a tree, by manipulation in five months, and without chloroform. In fact, manipulation does away with the necessity for anæsthetics. Dr. Stapleton had also reduced a dislocation on the dorsum ilii in the same way.

Mr. **Croly**, replying, said he was familiar with Bigelow's drawings and his ligament; but though Bigelow had worked at it, the credit of the method was ascribed by most surgical authorities to Reid. It was satisfactory to find that manipulation had succeeded with Prof. Bennett when stronger force had failed, and he therefore thought manipulation ought to be adopted. He had not referred in his communication to Mr. Wharton's case, the subject being confined to pubic dislocation. All the dislocations of the hip, except the very unusual ones, he had now seen. He saw Dr. Stapleton reduce a dislocation into the thyroid foramen by manipulation. He had himself put in the hip-joint by Colombat's method, of which he approved, that of leaning across a table. A great comfort of manipulation was that they could not do so much mischief with it as with pulleys, and every man had not a set of pulleys, or if he had he might not have posts to put them on. Besides, dislocations might have to be dealt with on board ship or on the field of battle.

### REMOVAL OF UTERUS AND ONE OVARY.

Mr. **W. Thornley Stoker** read a communication on a successful operation he had performed of hysterotomy through the abdominal wall.

Dr. **Atthill** was glad the operation had turned out so successful, and believed it was fully justified. The woman had been twice under his own care in the Rotunda Hospital. She was anxious that the operation should be performed. Twice had he refused to operate, though not from any doubt that the case was uterine. On careful examination in the first instance he had arrived at that conclusion. Having inserted the trocar of an aspirator, he satisfied himself that the tumour was solid or very nearly so, and told her that the operation would be hazardous. She had no obstruction of the bowels or difficulty in passing urine, and hence he did not consider the operation would be justifiable. Subsequently she came under the care of Mr. Stoker. But in the interval that elapsed her condition had not improved, so that he thought the operation was perfectly justified. The question of drainage tubes was one of great importance; he had found them productive of great benefit. At the same time he was not satisfied that it would not be better to dispense with them. A still more important point was that of nutritive enemata. He believed it was a means of feeding patients which was not sufficiently adopted. He fed a patient with nutritive enemata for nearly 21 days. The patient whom he operated on last Tuesday had not tasted any food since, but had been fed with nutritive enemata. Her digestive functions were easily disarranged, and he thought it advisable to give her nothing except a little champagne and ice. The less given the digestive functions to do in an operation like the present, which was the same as ovariotomy, the better; and he believed the patient could be kept nourished sufficiently without being given anything by the mouth. His patient for four or five days did not even take ice. She had had black vomit for many days. Perhaps the most important means of checking the vomiting after the operation was a hypodermic injection of morphia. He did not believe that medicines had produced any effect. He had obtained better results from pepsine wine. Keith gave carbolic acid in solution of acetic acid, but he had not found it beneficial.

Dr. **Kidd** said the first two or three times he examined Dr. Stoker's patient—he examined her a dozen times or more—he thought the tumour was ovarian, but long before the operation was decided upon he doubted the accuracy of the diagnosis, and balancing the evidence as carefully as they could, Mr. Stoker was correct in stating that they could not pretend to say exactly whether it was ovarian or uterine. However, Mr. Stoker approached the operation with all the preparations made for removing a uterine tumour, and the result showed that it was uterine. He believed the tumour had undergone a considerable change from the time Dr. Atthill saw the patient until she was admitted into Richmond Hospital. The outgrowth which lay at the umbilicus, described by Mr. Stoker as about the size of the fœtal head, had not appeared when Dr. Atthill saw the case. That outgrowth was the cause of the greatest part of the difficulty in the diagnosis. It could be moved from side to side through the abdomen without apparently moving the larger tumour. The first impression was that it was a separate tumour from the larger one. After repeated examinations, however, they found it was not a distinct tumour, but that it was part of the large tumour; and that was the first step gained in the examination. They had then a large tumour, filling the greater portion of the abdomen, and an outgrowth from that tumour, and the outgrowth could be pushed from side to side, causing the larger tumour to rotate. That was a condition he had frequently observed with an ovarian tumour, but never with a uterine tumour before, nor did he know that such an observation was on record with regard to a uterine tumour. There was a woman in Dublin some years ago, that perhaps every hospital surgeon present knew and saw; for he believed she had been in every hospital in Dublin. She was in the Coombe a considerable time. She had a large tumour filling the abdomen; she had an outgrowth not quite so large as the present instance, attached to the upper portion of the tumour, and which could be played from side to side in the abdomen. She had been in the City of Dublin Hospital, where through the courtesy of Mr. Tufnell, he first made her acquaintance. In showing the case, Mr. Tufnell described it in expressive words, that he would never forget—"you can shoot the small tumour like a weaver's shuttle from side to side through the abdomen." That was exactly the fact. They were all of opinion that it was a separate and distinct tumour; he did not think anyone who saw the case was aware that it was merely an outgrowth from a large tumour. After many months she came in a dying state to Coombe Hospital. He took her in, and was glad to get her, and keep her till she died, when they had an opportunity of making an examination, which resulted in the discovery of a large ovarian tumour, with an outgrowth from one side of it, and it was that outgrowth they observed like a weaver's shuttle shoot from side to side. The large tumour was so smooth, and the two layers of serous membrane played so freely on one another, that when the hand was placed over the abdomen they could not recognise the movement. The woman had been killed by the mobility of the tumour—whether by herself or others, the whole mass had been turned round, the pedicle got twisted, strangling the tumour, so that she was suffering from fever, produced by the putrefaction of the large mass. That case was fresh in his mind, when he got into the Coombe another case of large tumour with an outgrowth upon it, that he could shoot freely through the abdomen. On operation it proved to be an ovarian tumour, with an outgrowth upon it, and perfectly smooth walls, that allowed the movement to go on, without being distinguished by the hand. He saw a third case of ovarian tumour, with precisely similar characteristics. When this case first came before them it seemed that the only condition that would account for the mobility of the small outgrowth was that it was a separate tumour with a long thin pedicle. They then ascertained that it was not a separate tumour, but an outgrowth of the parent tumour, and they proved that the large parent tumour moved with it. So they had a large tumour that could be caused to revolve in the abdomen, and it seemed to him the only thing that could account for this was that it had a long, thin pedicle, such as an ovarian tumour frequently presents. That gave rise to a great doubt as to the nature of the tumour. In many other respects it corresponded to a uterine tumour; but he never knew a uterine tumour with those characteristics. Having examined it carefully with the sound, they found the uterus was of the normal length, that they could trace the whole posterior wall of the uterus, and a great part of the fundus through the rectum utterly free from the tumour, and of the natural contour and size. That was another difficulty. They next found when they rotated the small tumour the handle of the sound moved in the opposite direction to that in which the small tumour moved. That was another fact that he believed had never been observed before in the history of uterine or ovarian tumours. So far as his experience went, such a fact had not been put upon record until this case, and to account for it gave a good deal of anxious consideration. They had a movable tumour with, they believed, a long narrow pedicle, but disobeying all the laws of uterine tumours hitherto observed, namely, when moved the handle of the sound rotated in an opposite direction to that in which the tumour moved. Many suggestions were made. For a time the most feasible explanation was that, before the tumour, supposing it to be ovarian, had risen out of the pelvis into the abdomen, it had formed some adhesions to the opposite side of the uterus which caused it when the tumour was revolved to move in the opposite direction. The evidence was still in favour of its being an ovarian tumour. On a subsequent examination however, they found that with the sound in the uterus, and with the fingers of one hand in the vagina and the other hand over the abdomen, they could move the large tumour. Hitherto they had had no means of moving the large tumour. But now they found that the handle of the sound rotated in the same direction in which the large tumour moved. This at once changed their view; they had the movement of the sound in accordance with the laws of uterine tumours. So whatever opinion be entertained before he expressed a tolerably decided opinion to Mr. Stoker and the surgeons of the Richmond Hospital that the tumour was in all probability uterine, though he could not undertake to say with absolute certainty whether it might not be an ovarian tumour with a uterine complication. But he distinctly withdrew his opinion that it was an ovarian tumour. It was then decided to operate. Mr. Stoker had already given the details of the operation. One of his colleagues exclaimed as soon as the tumour was exposed, "it is an ovarian tumour;" because he could feel the fluctuation of it. The operation was completed. The result they had all heard. When the tumour was removed they at once saw the reason of the peculiar rotatory movements it presented. About the centre of the posterior wall there was a long conical prominence, which had formed a socket for itself in the left lumbar region, beside the kidney, and on this, as on a pivot, the tumour rotated, so that when the outgrowth at the upper part moved to the right the uterus at the lower part moved to the left, carrying the sound with it. As to diagnosis, it was one of the most instructive cases he had ever seen. Dr. Atthill did not obtain fluid; but he had seen several ovarian tumours tapped without obtaining fluid.

Professor **Bennett** pointed out that in a uterine tumour, if the vagina or uterus were not tied as a pedicle, and antisepticised and disinfected immediately before the operation, it would be a failure.

Mr. W. **Thornley Stoker** replied. Dr. Kidd's recollection was surprisingly accurate—towards the time when the operation was to be performed, they had made up their minds that it was probably a uterine tumour, but that possibly it might be ovarian. The instruments to remove the uterus were all on the tray during the operation. He fully endorsed Dr. Atthill's remarks on the importance of nutritive enemata. The value of pepsine wine he could not speak of from his own experience; but during the summer months he had had extensive opportunities of treating sea sickness, and there was no remedy he found of greater value than frequent small doses of pepsine wine. He endorsed what Prof. Bennett said on antiseptic treatment; but he did not go into the question as foreign to the scope of his communication.

The Society adjourned to the 16th inst.

## Special.

### FRANCE.

(FROM OUR OWN CORRESPONDENT).

Paris, Jan. 23.

*The Stigmata of Maize,* of which there was a short notice in the *Medical Press,* Jan. 14th, seems to gain partisans in this country. Its diuretic properties are being much experimented upon, giving, as usual, contradictory results. This new remedy was brought under the notice of the profession about six months ago, by Dr. Bafaud, who, practising in the Landes, observed that peasants freely used an infusion of the stigmata for attacks of gravel. But it appears that in Mexico the colonists used it in vesical catarrh from time immemorial. Recently the French medical press have received numerous communications upon the stigmata of maize, and many articles have been published, the last of which is one from Dr. Landrieux, who cites two cases in proof of its diuretic properties—the first, that of an individual attacked with ascites consequent on cirrhosis. Under the influence of the drug, given in the form of syrup, the quantity of the urine arose progressively and rapidly from 500 grammes to 1,200 and 1,500 grammes. On continuing this treatment for about three weeks, all ascites disappeared. The other case was that of a woman, aged sixty-eight, the subject of heart disease. There was considerable œdema of the lower extremities, enormous ascites, pulmonary congestion, renal congestion, causing a considerable diminution of the urinary excretion. The stigmata of maize was administered with the result of increasing the quantity of urine from 200 to 800 grammes in twenty-four hours. The œdema and the ascites disappeared in a short time. Dr. Landrieux terminates his article with the following conclusions:—1st. Not only the different preparations of the stigmata of maize are useful as a modifying agent of the urine, but these same preparations can be equally considered as an incontestible diuretic agent. 2nd. Diuresis is rapidly produced. 3rd. The pulse becomes regular under its influence, the arterial tension increases, while that of the veins diminishes. 4th. Complete tolerance of the drug, and in chronic cases the treatment might be continued during a month or six weeks without the slightest inconvenience.

A discussion on the effects of the drug took place lately at Montpellier. M. Caston, Professor at the Faculty of Montpellier, believed that it acted less as a diuretic than an *anesthésique local,* while M. Deuncé, of Bordeaux, thought it had an action *élective* on the mucus membrane of the bladder, but all agreed that it eased the pain in renal colic. At all events, it is worth a trial, being cheap and easily procured. The dose would be eight grammes for a pint in infusion to be taken *ad libitum.*

*Oxalic Acid in the Treatment of Diphtheria.*—Dr. Corilleau, writing to the *Revue Medical,* strongly recommends this drug. The mode in which he employs it as follows: oxalic acid, a gramme and a-half; syrup of oranges, 30 grammes; infusion of green tea, 120 grammes. A dessert-spoonful every three hours. Upon eighteen cases in which he adopted this treatment he lost but one.

A young resident physician has just succumbed from diphtheria contracted in attending a child affected with this disease in the *Hopital des Enfants Malades.* Only an hour before his decease the President of the Republic sent him the Cross of the Legion of Honour.

*A Case of Chronic Poisoning by Hydrate of Chloral* is reported by the *Journal de Pharmacie.* A man, æt. 47, took regularly every day for six years two grammes of bromide of potassium and two grammes of chloral for spasmodic retention of urine. He increased the dose of chloral gradually to twelve grammes a day. His intelligence and memory became weakened; he could no longer walk, being seized with trembling in the lower extremities; speech was difficult, and insomnolency deprived him of all rest. On entering hospital he was put under a treatment consisting of tonics containing strychnine, out-door exercise, and a strong diet. At the end of three months the cure was complete.

Registered for Transmission Abroad.

## DOES THE GENERAL MEDICAL COUNCIL REPRESENT THE MEDICAL PROFESSION?

### AN ANALYSIS OF ITS CONSTITUTION.

As the General Medical Council is about to be entrusted with new and most important functions in connection with medical education—the forming and revision of conjoint examination schemes, and the administration of an untried and altogether original system—the constitution of that conclave has come to be a burning question. To speak briefly, the General Medical Council has, throughout its twenty years of life, proved itself a dead failure, a discouraging disappointment to those who constituted it, a discredit to those who were members of it, and a source of apprehension to those who look forward to its place in medical affairs. While everyone respects the *personnel* of the Council, and feels that each member of it has been selected for his capacity, for the representation of the interests reposed in him, and for his true loyalty to those interests, everyone, nevertheless, is conscious that in the aggregate the Medical Council is completely inefficient. Being obliged to criticise unfavourably the constitution of the Council as a whole, we feel it but just to express our feeling not only that its members are individually irresponsible for its inefficiency, but that they are men of integrity, anxious to do their representative duty to the best of their ability, and, speaking generally, creditable representatives of the Bodies whose delegates they are.

The failure of the Medical Council was the failure of the mind which constructed it, and not of the members who formed it; and if a remedy for its unsatisfactory performance of its functions be found, it will be by a reform of its constitution, not by a change of its constituent members.

About this time last year, in anticipation of the meeting of the General Medical Council and the Select Committee of the House of Commons, we laid before our readers an incomplete analysis of the existing constitution of the General Medical Council, our purpose being to show, upon evidence, that the Council as at present formed can have no pretension to represent the medical profession, and in point of fact does represent interests which are, in some respects, at total variance from those of medical practitioners at large. The analysis of the constitution of the Council which we then undertook we were unable to complete, the remaining portions of it being jostled out of our columns by the lengthened reports of the proceedings of the Medical Council and of the Select Committee, and by indispensable comments thereon; and we then thought it more judicious to defer the whole subject to the eve of a new medical reform campaign rather than weaken the interest in it by debating it when the subject was in hibernation.

In anticipation of the re-assembling of Parliament, and reappointment of the Select Committee, we now propose to dissect the Medical Council for the behoof of those whom it may concern, and we take leave to reproduce much of that which we printed a year ago.

It has been roundly stated by certain champions of the General Medical Council (who, it would seem, are not easily discouraged in argument), that the Council is admirably representative of the profession, a faultless reflex of the needs and the opinions of medical men, and therefore superior to the necessity for any reform, and it is for those who advocate reconstruction, as we do, to prove our assertion that neither the medical profession nor the public have any distinct voice in the deliberations of the Council, or any material control over its acts.

The General Medical Council consists of twenty-four persons, each of the licensing bodies being separately represented, except that one member represents jointly the two Universities of Edinburgh and Aberdeen, and one member the two Universities of Glasgow and St. Andrews. In addition to the seventeen delegates from these institutions there are in the Council six members appointed by the Crown, and an additional member, the President, appointed by the twenty-three members—the total number thus being twenty-four.

The members of the Council may for the purposes of our inquiry be divided into three classes:—

*a.* Those respecting whose election the profession has no voice whatever.

*b.* Those upon whose election the profession exercises only an indirect influence.

*c.* Those who are directly chosen by the voting members of the medical constituency.

### THE REPRESENTATIVES OF THE GOVERNMENT AND OF LAY GOVERNING BODIES.

In Class *a*, respecting whose election the profession has no voice whatever, come the Crown nominees.

It is quite unnecessary for us to say that these gentlemen are not only men of the highest professional distinction, but of unchallengeable honour and integrity. But these qualities, *per se*, cannot make them the best medical legislators who might be selected. They are placed in the seats which they occupy that they may act as independent voters, and thus to dilute the overwhelming power of the licensing bodies in the Council, and they are especially the guardians of the public interest against the self-interest of medical corporations. To fulfil this *rôle* with complete efficiency, they would need to be intimately acquainted with the wants of the public *quoad* the medical profession, with the existing systems of medical education, with the daily working of the medical licensing system, and with the needs and sentiments of the profession at large. Selected by her Majesty from the medical men who are best known as consultation physicians and who are nearest to the throne, it is not to be expected that they should possess these qualities, or that they should be anything more in the Medical Council than eminent representatives of medical respectability. Respecting the medical requirements of nine-tenths of the population of Great Britain, of the daily work of nine-tenths of the profession, of the educating of those who are to be the medical advisers of the next generation, they are likely to know little save that which they acquire from journalists or in after-dinner chitchat; and they have, therefore, neither the zeal for progressive improvement which animates those who feel the necessity for change, nor the energy which belongs to younger men or more active teachers.

But the disqualifications of the Crown nominees in the General Medical Council for their positions as representatives are not only these negative qualities; they are not, as a rule, either independent or unprejudiced in matters of medical education. Every one of them, as a perusal of the list will show, is intimately related to and interested in some licensing body. Three of the six are physicians *et preterea nihil*, two of them attached to the London University, and one of them a leading spirit in the Irish College of Physicians. Two others are bound to the London College of Surgeons in the strongest ties, and but one of the six is even ostensibly free from the attachment to or control of a licensing body.

Experience shows us that their efficiency as representatives of independent public and professional interests is overshadowed by their allegiance to the particular licensing body to which they are specially attached, and they can be hardly said to be answerable to any one for their votes.

The Crown nominees can hardly be said to be answerable to any one for their votes, for they hold their offices for five years, subject to a matter of course re-election, and it is found, as a natural consequence of such semi-responsibility, and as a general rule, that they have no sooner entered the Council-room than involuntarily they take sides as the supporters of some individual licensing body and some particular interest.

Be this as it may, they certainly do *not* represent the rank and file of the profession, and being, with two exceptions, leading consultants of a metropolis, they have little knowledge of, and therefore but a limited sympathy with, the wants or the difficulties of the working general practitioner.

Their knowledge of medical teaching, medical students, dissecting-rooms, and the "grind" is usually prehistoric —a reminiscence of the age when surgeons got their qualification by apprenticeship. They have heard, doubtless, of such people as parish surgeons, and have been told of counter-prescribing, unqualified assistants, contract doctoring, and other anomalous forms of medical practice; but their personal experiences for the thirty years past have been confined to a comfortable study, a leisurely consultation, a two-guinea fee, and a three months' holiday in summer; and, we suppose, they consider that it must be an imperfectly constituted mind which complains of the discomforts of provincial parish practice, or the difficulties of students and teachers, and which asks the General Medical Council for comfort or redress.

Being thus circumstanced we imagine that the Crown nominees will hardly claim to reflect the feelings or necessities of the profession at large, and thus one-fourth of the Medical Council may at once be struck out of the list of our representatives.

### THE REPRESENTATIVES OF NON-MEDICAL OR SELF-ELECTIVE GOVERNING CLIQUES.

The next section of the Class, over whose election the profession possesses no influence whatever, are those members of the Council who sit for the rotten boroughs of the Medical Parliament—*i.e.*, for the self-elective cliques which govern some of our licensing bodies.

From a list of the "Medical Authorities" and their elective constituencies, which appears in the Report of the Medical Officer of the Privy Council for the year 1871, and which has been recently revised up to the present date by Mr. Miller, the Registrar of the Council, we cull the information requisite for illustration of our meaning.

*Licensing Bodies which give the Members of the Body no Voice in Election of a Representative.*

| Name. | By whom representative elected. | Number of Electors. | By whom electors appointed. |
|---|---|---|---|
| 1. Apothecaries' Hall, London | The Master, Wardens, &c., under Charter of James I. and Act 55 George III. cap. 194 | 24 | Themselves |
| 2. University of London | The Senate ... | 36, of whom 10 only are medical men | The Crown |
| 3. Universities of Edinboro' and | Senatus Academicus | 37, of whom 12 are medical men | The Crown and Board of Curators |
| Aberdeen | Ditto ... | 22, of whom 10 are medical men | Ditto |
| 4. Universities of Glasgow and | The Senate ... | 26, of whom 13 are medical men | Two-thirds by the Crown the rest by the University Court |
| St. Andrews | Senatus Academicus | 14 professors of whom (we believe) 4 are medical men | |
| 5. The Apothecaries Hall, Ireland | The General Court | Nominally 31 actually 15 | Themselves |
| 6. Dublin University | The Board of Trinity College ... | 8, of whom 1 is a medical man, the rest clergymen | Themselves by promotion |

Here, then, are eight licensing bodies out of the nineteen; and they return six representatives to the Medical Council. It will be seen that in the selection of these six representatives, 198 persons exercise voting powers, of whom (approximately) 105 are members of the medical profession. Striking an average, we find that each representative of these bodies in the Medical Council is supposed to speak the mind of (say) 17 medical men. But he may not be even thus far representative, for—in the election of a medical delegate from one of these bodies to the medical parliament—the medical voters are, in most cases, liable to be out-voted, two to one, by a phalanx of lawyers, political economists, mathematicians, and clergymen.

But if it be assumed that the medical profession has its own way in all cases, who does the representative represent? Nobody but the professors, and nothing but the school interests of his own particular college. The medical graduates, or licentiates, or fellows of these institutions are not permitted even a whisper as to who shall speak their opinions in the Medical Council, and, as a consequence, these six representatives enter the Council chamber as the advocates of themselves and of the pocket interests of their college or university, but, in no sense, as the exponents of the desires either of the public or of the medical profession, or even of the medical diplomates of that particular licensing body.

That these interests are not always deserving of representation, may be judged from the fact that one of these representatives is returned by the Apothecaries' Hall of Ireland. The "Body Corporate" of that institution consists, according to their Act of Parliament, of "the governor, deputy-governor, thirteen directors, and the subscribers," the licentiate Apothecaries of Ireland being wholly excluded from any voice in the management of the institution. The "subscribers" herein referred to are defined to be "not more than sixty judicious apothecaries, resident within Dublin or its suburbs," who have contributed £100 each to the establishment of the Hall. These subscriptions to the founding of the Hall were expended more than 100 years since in the erection and furnishing of what is neither more nor less than a drug shop, and many of the shares are held by widows and other non-professional persons who receive the income from them under cover of some friendly director. Thus, the "Body Corporate,' which elects the representative of the Irish Apothecaries' Hall in the General Medical Council, consists actually of about 15 persons. The institution itself is utterly effete —grants an insignificant number of very inferior qualifications at a nominal fee, and if ever so well constituted is entirely disentitled from expressing an opinion as to medical affairs.

It is, we assert, an outrage on common sense that the nominee of fifteen shareholders in a drug-shop—of eight respectable elderly clergymen, or of three dozen barristers and men of science—should be put to the task of legislating for the education and registration of the medical profession.

*(To be continued.)*

## ARSENICAL WALL-PAPERS.

Having repeatedly directed attention to the evils attendant upon the unrestricted use of arsenical and other poisonous materials in our manufacturing processes, it is very satisfactory to ourselves to find the question about to be taken up by a no less influential body than that of the Society of Arts. On Wednesday evening last the members of this Society were very usefully engaged in discussing a paper read by a gentleman who has given a good deal of attention to the subject.—Mr. Henry Carr on "Our Domestic Poisons." Mr. Carr restricted himself chiefly to the use of arsenic in wall-papers, cotton fabrics, artificial flowers, &c., although it is known to enter into a vast number of ornamental and useful materials, and he at the same time furnished numerous well-authenticated instances of poisoning, some of which were attended with fatal results — many of the more remarkable instances occurring to members of our profession, who in the first instance have persistently refused to believe that the very minute quantity of arsenic given off by a wall-paper was capable of producing serious results. But so it is, and the question naturally arises why so deleterious a substance should be extensively used in the arts and manufactures. The answer is simply that it increases the profits of the manufacturer and dealer. A certain class of lighter and more attractive articles can be produced at a lower price. Arsenic imparts a permanency, brilliancy, and body to thinner and cheaper papers, which are made to resemble the more expensive and better kinds. The colour in connection with which arsenic is principally found is green; it enters, however, into a variety of other colours, as reds, browns, blues, pinks, French greys, blacks, &c., and, being a surface colour, it is easily separated, and becomes a source of considerable danger. Paper-stainers assert, however, that there is no economy or advantage in using arsenical pigments, but that they cannot help themselves, since the best colours are imported from the Continent, and are not to be had free from arsenic. If this is so the trade would suffer little or no injury if an Act of Parliament were passed altogether prohibiting the use of arsenic or other poisonous substances in our English manufactures. The foreign trader would no doubt be seriously prejudiced by prohibition, and it comes to this—should foreign colour makers be permitted to carry on an illicit trade by the exportation of poisonous pigments into England whilst their own laws strictly prohibit their sale and use? This question, if we may judge by the course pursued with regard to the opium trade, the Sale of Poisons Act, and the Adulteration of Food Act, seems to be finally settled in the public interest. If, therefore, manufacturers see fit to continue to use poisonous pigments, they should be compelled to stamp their productions in plain characters, "arsenic poison." It is, in our opinion less culpable to sell a mixture of coffee with chicory, or of milk and water, for the genuine articles, than to sell wall-papers *warranted* free from arsenic, but which at the same time are known to be loaded with it. The subject is undoubtedly one of vast importance to the community in general, and calls for Government investigation and interference; and in any measure brought forward professing to deal with the evil, the retail vendor should be made responsible in the first instance, every facility, of course, being accorded to him for shifting the blame to the shoulders of the paper stainer or colour manufacturer, so that the real culprit should be reached and made amenable to the law. Public attention has now been fairly aroused on the question. The Medical Society of London some months since appointed a special committee to investigate the subject, with a view of bringing the matter under the consideration of the Local Government Board, and now we have the Society of Arts expressing its willingness to co-operate and consider what scope the proposed legislation should take, so that a stop shall be put to a dangerous and insidious form of domestic poisoning.

◆

# Notes on Current Topics.

## The Irish Prison Surgeons.

We noted last week the fact that the "Departmental Committee," to which was entrusted the consideration of the remonstrances of the Irish prison surgeons against the arbitrary and illegal impositions of the Irish Prisons Board, had sent in their report, and we expressed our belief that we should soon hear something of the determination of the Government upon the arguments urged by the medical officers. The first outcome of this report appears this week in the shape of the following :—

General Prisons Board, Dublin Castle,
19th January, 1880.

Sir,—I am directed by the General Prisons Board to inform you that they have recently had under their consideration the important question as to the expediency of closing a certain number of prisons in Ireland, with the object of effecting a saving of expense and improving the prison system, as contemplated by the Prisons Act, 1877.

I have now to acquaint you that his Grace, the Lord Lieutenant, on the recommendation of the General Prisons Board, has decided on closing certain of the prisons in Ireland, by order issued under sec. 30 of 40 and 41 Vic. c. 49, from and after the 31st of March next, and that —— Prison shall be one of them.

Your services, therefore, will not be required after that day, but your claim to compensation or superannuation shall be carefully considered.

I am, Sir, your obedient servant,
RICHARD CLEGG, Chief Clerk.

This letter, so far as we know, has been addressed to the surgeons of the prisons at Longford, Carlow, Enniskillen, Lifford, and Downpatrick, and probably will be forwarded to others whose disestablishment is determined on. This step is, of course, perfectly within the discretion of Government, and the medical officers thus removed from office must only fall back upon their superannuation rights. The extent of those rights, and their application to individual medical officers, will vary with the dates and other circumstances of appointment, and will depend upon the interpretation by counsel of the clauses of the Prison Officers Superannuation Act of 1873, and of the New Prisons Act bearing upon that question. We shall next week look into these points, but meanwhile we would suggest that the Irish prison medical officers should determine, upon the best legal authority, their rights, which it is quite likely they may have to assert. The attitude of the Government with reference to the County of Dublin Prison at Kilmainham is deserving of a special narrative for itself, as an illustration of the audacious assumption of arbitrary power which the Treasury and Government departments take upon themselves in contemptuous defiance of both law and equity.

It may be remembered that, about twelve months ago, Dr. R. Kirkpatrick, the then surgeon of the prison, asked for leave, and Dr. Fitzgibbon was thereupon, on his nomination, approved by the Prisons Board as his substitute.

After a short period Dr. Kirkpatrick, not desiring to retain his office, resigned it formally, and Dr. Fitzgibbon was continued in office—though, as we believe, without any formal appointment—being recognised as the medical officer in all official communications, and paid his salary without reference to Dr. Kirkpatrick. It would seem as if, during this period, the Treasury was hatching out a project *to force the medical officers of the city prisons to do the additional work of the county prison without any extra pay*, and thus to save the cost of a medical officer for Kilmainham. We are, at least, we believe correct in stating that these medical officers have been plainly and rudely told that a medical officer for Kilmainham Jail will not be appointed, and that, if they refuse to do this extra duty, they will be dismissed from their appointments in connection with the city prisons, and they have been told this without a word being said as to pay being given for such extra duties. We have a difficulty in finding words to characterise the conduct of a Government department which endeavours to force extensive additional duties upon their officers under threat of expulsion. Such a proceeding is insulting in its arrogance and contemptible in its meanness; but in this instance it is worse, it is wholly illegal and a ridiculous blunder. The medical officers of the city prisons have their rights strictly defined by the terms of the Prisons Act, and are in the position, so far as we know, of snapping their fingers, if they please, at the Prisons Board or the Treasury underlings, or even at the First Lord himself; and it is a piece of unexampled departmental stupidity to permit the issue from the Treasury Office of threats which the department has no power whatever to carry out.

We think it right to express our belief that, in matters such as this, the home departments of the Irish Government are not directly to blame. In all questions of money they are obliged to take their orders from the Treasury, and are allowed no discretion as to the orders that the Whitehall magnates please to give. The officers at Dublin Castle may be thus frequently obliged to reflect a policy of which they disapprove, and orders which they know to be foolish and illegal, and they ought not, therefore, to be laden with the entire responsibility for the ludicrous departmental incompetency displayed in transactions such as that to which we have referred.

## A New University.

SOME discussion is being excited by a proposal to create a *new* University in London on lines that will differ very much from those by which the present institution in Burlington Gardens is distinguished. The proposition, so far as it has form in the minds of its originators, is one for the amalgamation, under a central government, of the total number of medical schools in the metropolis, the directorate being, presumably, to be composed of representatives from each school. The idea is one that will receive undoubted encouragement from those who are not blinded by a partial admiration for the University of London. It undoubtedly embodies many defects, and it is now, more than ever, necessary for the well-being of the medical profession that a hard and fast stand should be made against a system the working of which is injurious to its best interests. It is impossible to conceal the truth that the London graduate, although a highly-cultivated individual, is, as a rule, not an experienced practitioner; and this wholly in consequence of the theoretical nature of the examination he is submitted to. The one complaint against the London degree is that embodied in the term by which the old school contemptuously designates it, "dreamy," and though we do not entirely accord with the sweeping condemnation it receives at some hands, we do urge that its character needs to be radically altered ere it can hope to become a favourite test with candidates. We do not think it too hard, we only deem it hard in the wrong direction. And as there seems little to hope for in the way of improvement from within the councils of the University, there is no resource but to contest its influence by pitting against it a rival founded on a better and more professional basis.

## Health of Kensington.

THE medical officer of health for Kensington has just issued his final report and summary, for the past year, on the health of Kensington. This is highly satisfactory in most important respects, and indicates that the parish is under very favourable hygienic conditions. The annual death rate is lower than that of 1878, and only a trifle higher than the exceptionally low rate of 1877; the death rate from zymotic diseases is, however, the lowest recorded in the decade, and is a subject for hearty congratulation, as showing the good effects resulting from the energetic action taken in pursuance of a hygienic *régime.* It is worthy of note that the death rate for December is 19·6, while the average rate for the past ten years has been as high as 21·6 per thousand. Dr. Orme Dudfield reports that only one uncertified death has been registered, that being the case of a child ten days old, who died from unascertainable causes.

## The Gilbert Blane Medal.

Sir Gilbert Blane, physician-in-ordinary to George III., left money for the founding of two gold medals, which were to be awarded biennially for medical works. The adjudicators are, this year, Dr. Risdon Bennett, as President of the Royal College of Physicians, Dr. Luther Holden, as President of the Royal College of Surgeons, and Sir Alexander Armstrong, as late Director-General Navy Medical Department. The successful competitors are Staff-Surgeon H. F. Norbury, C.B., M.R.C.S., L.S.A., H.M.S. *Active,* and Staff-Surgeon W. D. Longfield, L.R.C.P.I., H.M.S. *Tenedos.* Both have seen service recently in South Africa.

## Habitual Drunkards.

The Earl of Shaftesbury has consented to preside at a meeting to be held in the rooms of the Social Science Association, Adam Street, Adelphi, on Monday next, Feb. 2, at 8 p.m., when a paper will be read by Dr. Stephen Alford on "The Habitual Drunkards Bill, 1879; the class of persons for whom it is intended, and how it may be administered; with an account of a recent visit to the American Inebriate Homes;" to be followed by a discussion, to which all members of the profession interested in this important subject are invited. The subject is of great moment, and from Dr. Alford's experience and the valuable information his paper is likely to contain, should attract a large sprinkling of the profession. In connection with this subject may be mentioned a proposal to form a society for the establishment of inebriates, asylums or, as it is, there is a talk of calling them neuropathic homes. We believe this will also occupy the attention of the meeting, and circulars are being prepared giving all necessary particulars.

## An Improved Form of Sugar Test.

Dr. Pavy exhibited on Friday evening at the Clinical Society a greatly improved form of the copper test for sugar. Every one who is accustomed to the examination of urine has experienced the vexation of finding the Fehling's solution used for the purpose in a state of reduction and unavailable. The plan adopted to prevent this inconvenience by Dr. Pavy is to compound the ingredients of Fehling's solution in a solid form, and he has devised a method by which the potash is prevented from abstracting the water of crystallisation of the sulphate of copper, and so destroying the whole. In the preparation of the substance, the materials are isolated from immediate contact and cast into pieces about the size of ordinary pills. They can be kept for an indefinite period in a corked bottle, and will be of great service to medical men who require to make use of the sugar test away from their own surgeries. But at any time, and in any place, they are an elegant substitute for the rough-and-ready testing by means of copper sulphate and potash, while being always reliable. The pellet—one being used for each sample of suspected urine—is to be dissolved over heat in about a drachm of water. It then assumes the deep blue colour characteristic of the alkaline solution of copper salt, and to it must be added about the same quantity of the urine to be tested. The reaction is precisely as with the test in ordinary use, the copious precipitate of foxy-red suboxide of copper at once appearing if the urine contains sugar.

The pellets are prepared by Mr. William T. Cooper, pharmaceutist, 26 Oxford Street, and are sold by him in bottles containing twenty-four each for a shilling.

## Death through Chloroform.

Dr. Thom, of Brampton, died on Monday last, from the effects of inhalation of chloroform. For many years the deceased had been in the habit of employing the anæsthetic to procure sleep, and seems to have used it with the same intention on the last fatal occasion. Dr. Thom was a universal favourite in and about Brampton, and his loss will be very severely felt. It is impossible to disguise the fact that medical men are too prone to resort to means for procuring rest to themselves that they would not advise to their patients, knowing the danger they involve; and this latest case of accidental death is an illustration of the grave consequences that may follow from the continual employment of narcotics. At the inquest on Monday Dr. Elliott, the city coroner for Carlisle, called attention to the importance of legislative restriction on the sale of chloral, and many cases of chloral poisoning within the experience of the jury were recalled by them.

In connection with this subject we think it well to correct a view which is seemingly entertained by our contemporary the *Pharmaceutical Journal.* It accuses us of abusing chemists as a class. Nothing is farther from our thought. We have distinctly avowed our conviction that they are a useful adjunct to the medical profession, and, as a rule, an honourable and rightly-intentioned body of men. But we must continue to aver that the sale of dangerous drugs, destructive as they prove to be, ought to be restricted within fast set limits. This is no attack on the chemist, but a plea for public safety. The plan we propose will not degrade, but exalt the position of the chemist, and we are sorry that our contemporary so wilfully misunderstands us.

## The New Registrar-General.

In our last number for 1879 we expressed regret at the unmitigated "job" which had been perpetrated by the Government in the appointment of Major Graham's successor to the post of Registrar-General. Last week a letter was addressed to the Prime Minister on the subject by Mr. Nelson Hardy, F.R.C.S., the reply to which is as lame as official utterances usually are. The Earl of Beaconsfield is higly sensible of, and knows how to appreciate the many public services rendered by Dr. Farr during his past career, but that *her Majesty's Government had excellent reasons for the course which they considered it their duty to take.*

Of course a Government must have "excellent reasons" for everything it does; but to the uninitiated it may perhaps throw some light on the subject if we mention that the new Registrar-General, besides having acted as private secretary to Mr. Sclater-Booth, is a relative of the Duke of Rutland, of Lord Henniker, and of Lord John Manners, the Postmaster-General. This may be a qualification in the eyes of H.M. Government, but the profession and the public will look at the appointment through another pair of spectacles, and will not readily pass over such an act of injustice to a valued public servant by the substitution of a gentleman whose name is entirely unknown as that of a scientific man outside the ranks of his own immediate friends.

THE Lord Chancellor of Ireland has been appointed Vice-Chancellor of Trinity College, Dublin.

MR. HENRY J. L. GRAHAM, who has filled the office of Principal Secretary to the Lord Chancellor since 1874, has been appointed by the Lord Chancellor to succeed Mr. Barlow as Master in Lunacy.

SIR WILLIAM MILLER, Kt., M.B. Dub., who has thrice served the office of Mayor of Derry, and now holds the surgeoncy of the County Infirmary, has been placed upon the Commission of the Peace for the borough of Londonderry.

OF the 140 candidates examined at the College of Surgeons, London, during the past fortnight, 42 failed to satisfy the Board of Examiners, and were referred for three, and 9 candidates for six months' further anatomical and physiological study.

FROM an American contemporary we learn that "The older medical schools of St. Louis are crowded with students. The prospect of more stringent requirements in the near future is evidently having its effect also in driving the more timid to school *while diplomas can still be easily obtained.*"

AT the fortnightly meeting of the Metropolitan Asylums Board on Saturday last, it was resolved that Dr. Thomas Birch Dyer, at present assistant medical officer of the County Lunatic Asylum, Colney Hatch, be appointed medical officer to the Adult Asylum, Darenth, on probation for three months, at a salary of £400 per annum.

THE annual death-rate from the seven principal zymotic diseases in the large towns ranged from 0·4 and 0·5 in Leicester and Brighton, to 7·7, 8·8, and 9·0 in Hull, Dublin, and Plymouth. Measles showed exceptional fatality in Plymouth, Hull, and Nottingham. The largest proportional excess of scarlet fever occurred in Dublin, Norwich, and Sunderland; of whooping-cough in Newcastle-upon-Tyne, Salford, and London. Small-pox caused 4 more deaths in London, 7 in Dublin, but not one in any of the other large towns.

IN the principal foreign cities the rates of mortality, according to the most recent official weekly returns, per 1,000 of the population, were — in Calcutta 35, Bombay 38, Madras 39; Paris 33; Geneva 24; Brussels 37; Amsterdam 37, Rotterdam 32, The Hague 36; Copenhagen 28; Stockholm 18; Christiania 12; St. Petersburgh 41; Berlin 26, Hamburg 30, Dresden 27, Breslau 26; Vienna 33; Buda-Pesth 38; Rome 41, Venice 44; Naples 35, Turin 36; Alexandria 40; New York 24. Small-pox caused 61 more deaths in Paris.

◆

## Scotland.

**DEATH FROM CHLOROFORM.**—The Procurator-Fiscal (Mr. R. L. Stuart) has been engaged in precognoscing witnesses regarding the death in the New Royal Infirmary, Edinburgh, some days ago, of James Blair, baker, Aberlady, Haddingtonshire, while under the influence of chloroform, administered by Mr. Silke, one of the house-surgeons. The deceased, who is said to have been a healthy, cheerful-looking person, 45 years of age, had, while chopping wood with an axe, cut off a portion of his forefinger, and it was in connection with the treatment of this injury that the anæsthetic was employed. In a letter to the *Haddingtonshire Courier* Mr. Silke has written an account of the occurrence, and adding, that after full inquiry by the Procurator-Fiscal, the medical officer of the Police, and the infirmary authorities, no blame has been attached to him or to anyone in connection with the matter.

**EDINBURGH EYE INFIRMARY.**—The annual meeting of the contributors was held in the Infirmary on the 23rd inst., Dr. John Pringle presiding. The annual report stated that since the opening of the charity, twenty-eight years ago, 24,105 individuals had applied for advice, and of these 386 had been accommodated in the house for longer or shorter periods. During last year the applicants were 1,059, and the in-door patients 5 in number. A large proportion of cases were, as might be expected, of a severe character, many of them having been for some time under previous treatment. Upon an avarage, about a fifth part of the number applying for advice at the institution came from the country, and not a few from the remote districts of Scotland and the North of England. The whole of the officers act gratuitously. The managers earnestly hope that the public support will be continued, and that by an additional number of subscribers this year the annual expenditure will be kept within the income. The report was adopted.

**HEALTH OF EDINBURGH.**—For the week ending the 17th inst. the deaths fell from 93 to 74, giving a death-rate of 18 per 1,000. Diseases of the chest accounted for 44 of the deaths, and zymotic diseases for 14. Of the 139 births 10 were illegitimate.

**GLASGOW—A SICK CHILDREN'S HOSPITAL.**—The committee having charge of this scheme, now some time mooted in Glasgow, have secured premises suitable for a hospital, and it is contemplated to open the institution at Whit-Sunday next. The site, corner of Scott Street and Buccleuch Street, is most eligible, situated in the midst of the city, of easy access to the west, convenient to some of the most densely populated portions, yet unconfined and airy.

**GLASGOW ROYAL ASYLUM.**—At a meeting of the directors of this asylum, held on the 20th inst., Dr. Hector C. Cameron was appointed visiting physician in room of the the late Dr. J. G. Fleming.

**The Mortality in Glasgow.**—The deaths in Glasgow for the week ending Saturday, the 17th inst., were at the rate of 24 per 1,000 per annum, against 23 in the preceding week, and 27, 20, and 28 in the corresponding periods of 1879, 1878, and 1877.

**The Registrar-General's Returns.**—According to the weekly return of births, deaths, and marriages, the death-rate in the eight principal towns of Scotland, for the week ending January 17th, was 21·7 per 1,000 of estimated population. This rate is 5·6 under that for the corresponding week of last year, and 0·4 under that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 15·6, and the highest in Paisley, viz., 30·8. The mortality from the seven most familiar zymotic diseases was at the rate of 3·3 per 1,000. Whooping-cough continues the most prevalent of these diseases.

# Correspondence.

## POISON VENDING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your number for the 14th inst. I see that your pen is bearing down on that pharmaceutical Syren, Chloral, by calling attention to the spell under which a band of volunteers, or would-be protectors of the helpless, *appear* to have fallen. Let us hope, however, that the difficulty is not so great but that some modern Ulysses may yet rid us of, or save us from, this seemingly popular and seductive, but most deadly foe. On the last day of March, 1877, nearly three years ago, it was my painful duty to hold an inquest on the remains of an intelligent and useful man, destroyed in the prime of life abruptly and unexpectedly by this most dangerous and treacherous of narcotics, against the fatally pleasant influence of which so many of both sexes, of nearly all ages, and in all classes of society, prove so utterly helpless, that common sense and common humanity alike dissent from the hackneyed phraseology of those (and their name is "Legion") who exclaim "What! make people sober by Act of Parliament?" In reply to all such people it is surely enough to direct attention to our Parliamentary mode of dealing with any case of crime or of vice. Is it not *always* by Act of Parliament that we seek to repress the offence and to reform the offender? In the sad case to which I have referred (and I regret to say that it was not the first, nor has it been the last chloral inquest that I have had to preside over) the jury discreetly urged me to take steps for handcuffing this terrible agent. I explained how this might be done, and gladly undertook the task. I wrote to Mr. Elias Bremridge, the Registrar and Secretary of the Pharmaceutical Society, to invoke the aid of that Society in making application to the Privy Council. This was early in April, 1877. I shall now respectfully call the attention, Sir, of yourself and your subscribers to the Register of Pharmaceutists for 1879 or for 1880 for comparison of the date of my application and of the Pharmaceutical Society's application to the Privy Council; then to the promptitude of the Privy Council in giving effect to the Pharmaceutical Society's transmission of the message from the Carlisle jury, sent in April, 1877. In conclusion, I beg to draw your attention to the position assigned to chloral in the list of dangerous drugs, and remain,

Yours, &c.,

Robert Elliott, M.D., F.R.C.P.,
Coroner for the City of Carlisle.

# Literary Notes and Gossip.

A new book is announced from Glasgow, entitled "The Student's Primer on Urine," by J. Travis Whittaker, M.D. "Clinical Demonstrator to the Royal Infirmary, Inventor of the Tenometer," &c. The urinary organs have attracted a good deal of attention lately; during the past few months no less than four books have appeared with almost the same title. The best that has come under our notice is Tyson's "Practical Examination of the Urine." We have not yet seen the Glasgow primer.

⁂

Dublin is represented in medical literature this week, by an "Essay on Fatty Heart," by Dr. Henry Kennedy. The author is well known to our readers, and anything that emanates from his pen is sure of respectful consideration. We shall notice this book more fully, later on.

⁂

An opposition to Mudie's Library has been started. Like Mudie's, the new venture is a limited liability speculation, to be established under the title of the "Grosvenor Library," which, besides lending out books, will contain reading-rooms and other accommodation for its subscribers.

⁂

In an editorial in the first number for the new year of the *Boston Medical Journal*, announcing its altered form, and the reasons therefor, the writer confirms the view, expressed by us some time since, that "the day of quarterlies and monthlies seems to be passing away, the demand of the present time being for small quantities at frequent intervals."

⁂

The *Obstetrical Journal* of Great Britain and Ireland will in future appear on the 15th of each month, at the reduced price of one shilling. Hitherto it has been published on the 1st of the month, and at eighteenpence per number. Dr. Galabin has resigned the editorial chair, and is succeeded by Dr. Ernest Herman, of the London Hospital. It will still be published by Messrs. Churchill.

⁂

In our last column of "Literary Notes," we mentioned that, in consequence of the ill-timed interference of the lay treasurer of Guy's Hospital, and his desire that comments should be submitted to him for approval before they appeared in *Guy's Hospital Gazette*, the editors of that periodical had announced their inability to carry on the work under such a dictatorial *régime*, and the journal would be discontinued in consequence. Such dignified conduct has not been without its effect, and we have pleasure in congratulating those gentlemen "upon the re-appearance of their journal, though a week or two late.

⁂

In American medical literature the following changes occur from the commencement of the New Year. Dr. F. P. Foster succeeds Dr. Hunter as editor of the *New York Medical Journal*; the *Medical News and Library*, and the *Monthly Abstract of Medical Science*, have amalgamated under the title of the *Medical News and Abstract*. The "library" department of the News has been given up, and the clinical department enlarged. The *Richmond and Louisville Medical Journal* will, in future, be published in New York, and the title altered to *Gaillard's Medical Journal*. The *Boston Medical Journal* is issued in a new form, and without its customary wrapper. Another new journal appears under the title of the *Chicago Medical Gazette*.

⁂

The question of who is entitled to call himself "professor," is frequently cropping up in medical circles. In a review of the translation of Dr. De Wecker's book on "Ocular Therapeutics," a writer in the last volume of the *Westminster Review* gives his view of the question thus: "We observe on the title-page of the English edition of these lectures, that the author is styled 'Professor of Clinical Ophthalmology, Paris.' This is a slight flight of fancy. Dr. De Wecker has a free dispensary in a populous quarter of the French capital, which is open to anyone who may take an interest in ophthalmology, and who may be willing to listen to an occasional lecture. Dr. De Wecker is *always ready to profess when an audience is at hand*, but if this gives him the right to the title his English publishers bestow on him, every specialist in Paris is a clinical professor."

⁂

The eminent French physician and naturalist, Dr. Jean Charles Chenu, died recently, at the age of 71. His first publication was a treatise on Cholera Morbus (1835); his second an essay on Thermo-mineral Waters (1840). He next applied himself to the preparation of his great folio work, "Conchological Illustrations; or, Description and Figures of all Known Shells, Living or Fossil, with the new Genera and the latest discovered Species" (1842-1847). In 1852 he became librarian of the School of Military Medicine, was present during the Crimean campaign in connection with the ambulance service, and was director-general of ambulances during the siege of Paris.

⁂

During the past year 4,294 new books, and 1,540 new editions were published in the United Kingdom. Of these Educational, Classical, and Phitological claimed 828, Arts and Sciences 353, Geographical Research, Voyages, and Travel 298, History and Biography 403, Medicine, Surgery, and Allied Sciences 189, the balance here made up with novels, children's books, &c. In fact, with the exception of *Belles Lettres*, our art stands lowest on the list in point of numbers in the field of literature. What it lacked in quantity let us charitably hope it adequately supplied in quality.

⁂

It is announced that Liebnitz's long-lost calculating machine has been recovered. Liebnitz invented and constructed this machine in 1672, during his stay in Paris. It can add, subtract, divide, and multiply, and was the wonder of the time. This machine became the property of the Hanover public library, but long ago disappeared from among its treasures. All that was known about its disappearance was that it had once been sent to an instrument maker at Göttingen to be repaired. It has now turned up again in the Göttingen library, and through the efforts of Dr. Bodemann, the librarian of the Hanover public library, has again come into the possession of the institution.

⁂

New Books and New Editions.—The following have been received for review since the publication of our last list, Dec. 24:—"The Surgical History of the War of the Rebellion," Vol. I., Part II., prepared by Drs. J. K. Barnes and J. J. Woodward, Surgeon-General, United States Army. "Transactions of the Pathological Society of London," Vol. XIII. "The Year-Book of Pharmacy, 1879." "Triennial Report of the Saughton Hall Institution for the Insane." "Photographic Illustrations of Skin Diseases," Parts I., II., III., IV., by G. H. Fox, M.D. "Pay Hospitals and Paying Wards," by Henry C. Burdett. "Statistical Report of the Health of the Navy for 1878." "Youth, its Care and Culture," by J. Mortimer Granville, M.D. "Annual Report of the Broadmoor Criminal Lunatic Asylum." "The Relations of Cardiac Hypertrophy to Renal Disease," by R. Saundby, M.D. "Eyesight, Good and Bad," by R. B. Carter, F.R.C.S. "St. Bartholomew's Hospital Reports," Vol. XV. "The Obliteration of Port Wine Marks," by Balmanno Squire, M.B. "Hot-Air *versus* Hot-Water Baths," by R. Metcalfe. "The Essentials of Bandaging," by Berkeley Hill, F.R.C.S. Goodlee's "Atlas of Human Anatomy," Part XI. Witkowski's "Movable Atlases of Human Anatomy and Physiology," Part IV. "The Eye," by Henry Power, F.R.C.S.

# Obituary.

## DR. E. C. SEATON.

Dr. Edward Cator Seaton, of the Medical Department, Local Government Board, died on Wednesday last. The regret with which we make this announcement will be echoed by all who are familiar with the long and valuable services rendered by the deceased gentleman to the cause of hygienic reform. The continuous series of official reports issued from the department over which Dr. Seaton presided are admirable memorials of the skill and ability with which he discharged the duties of his office. In addition he leaves several personal works which testify to the undivided interest with which he regarded the labours he was engaged on. Among these the "Handbook of Vaccination," and the article "Vaccination" in "Reynolds' System of Medicine," are the most important. Dr. Seaton had been for some time in ill-health, but hopes were till very recently entertained of his ultimate recovery. Only a short time ago he resigned his post as Medical Officer to the Local Government Board in consequence of his failing strength, but the end was unexpected when it came. Dr. Seaton was a Graduate in Medicine of Edinburgh University, and became a Fellow of the Royal College of Physicians in 1872. He had been President of the Epidemiological Society, and at all times took the deepest interest in questions affecting the public health. In private life he was much esteemed, and his loss will be very severely felt by all who have come within the sphere of his kindly influence.

## DEPUTY SURGEON-GENERAL JOSHUA HENRY PORTER.

It is with very sincere regret indeed that we have to record the death of this most distinguished member of the Army Medical Department, who succumbed during the past week under an attack of pneumonia, contracted in the discharge of his arduous duties as chief of the medical staff employed in Afghanistan under General Roberts. By his premature death the Irish School of Surgery has been deprived of one of its brightest ornaments, and the forces now engaged in Afghanistan of one of their most-to-be-depended-upon medical officers. Mr. Porter was a native of Dublin, having been the eldest son of the late Joshua Porter, formerly High Sheriff of this city, and consequently first cousin of our distinguished fellow-citizen, Mr. Porter, Surgeon-in-Ordinary to her Majesty in Ireland, and nephew to Mr. Frank Thorpe Porter, well known for many years as a Police Magistrate of the city. Surgeon-General Porter commenced his professional career under the auspices of the late Professor William Henry Porter, to whom he served his time as an apprentice, pursuing his studies in Meath Hospital and in the School of the Royal College of Surgeons. In the year 1852 he became a licentiate of this college, and selected the army for his future career, his first commision as assistant-surgeon bearing date 15th June, 1853. Devoting himself with ardour to the zealous discharge of his duties, he so quickly distinguished himself that in the following year, for his services with the 97th Regiment before Sebastopol, he was decorated with three medals. In 1857-8 he was actively engaged in charge of the forces employed in suppressing the mutiny in Bengal, was present at the action of Nuzrutpore, Chanda Ummerpore, Sultanpore, at the siege and capture of Lucknow, and the storming of the Kaiser Bagh. In 1859 he served in the operations in Bundelcund, and was present at the surprise and night attack at the Kala Nuddy. For these services he received another medal with clasp, and in 1862 received promotion as full surgeon. During the Franco-German war he served with the British Ambulance Corps, was present at the siege of Paris, and in recognition of his eminent services was honoured with the German steel war medal. Returning to England, he was appointed Assistant Professor of Surgery at Netley Army Medical School, the onerous duties of which post he filled in a most exemplary manner. Multifarious as were his duties here he found time, however, to write an essay in competition for a prize offered by her Majesty the Queen of Prussia and Empress of Germany for the best essay on the "Practical Treatment of Wounded in War," and with such competent judges as Professor Billroth, of Vienna; Baron Von Langenbeck of Berlin; and Socin of Basle, in the face of competitors from all quarters of the globe, it can be no small source of pride to the School of Irish Surgery that the prize was awarded to the subject of this present memoir. In addition to this he made many and valuable contributions to the pages of the *Medical Press* and other medical journals, whilst he illustrated that which he taught by brilliant and successful operations in the wards of the hospital. In his despatch of the 22nd October last General Roberts recommends his name specially to the favourable consideration of his Royal Highness the Commander-in-Chief, so that to the last we find him "doing his duty," the highest praise that (as we have heard Surgeon-General Porter expressing himself) in his opinion could be awarded any person.

## DR. H. MOLONY.

We regret exceedingly to have to announce the death of Dr. Harry Molony, which occurred on Saturday last at his residence, Kilrush. The lamented deceased, who was eldest son of the late C. B. Molony, Esq., occupied the position of Medical Officer of the Kilrush Union Workhouse, and in discharge of the duties incidental to the position, as well as in private life, earned the esteem of all, especially of the suffering poor, of whose wants he was ever solicitous His many sterling qualities of head and heart rendered him a universal favourite, and his demise is regarded with feel ings of deep regret, not alone by his immediate friends and acquaintances in Kilrush, but by everyone outside it who knew his character or had the advantage and pleasure of his acquaintance.

◆

## DR. CHARLES BENSON.

THE lamented death of Dr. Benson, which occurred very unexpectedly on Thursday last, severs one of the last remaining links of our connection with the generation which is passing away, and his personal and professional attributes have made that severance more than ordinarily painful and suggestive. With Dr. Benson will have almost expired the era in the life of the School of Irish Surgery and Medicine with which great names have been associated, and which will be remembered as one of its brightest epochs. He was the contemporary and *confrère* of Houston, William Henry Porter, Arthur Jacob, Richard Carmichael, Robert Adams, Robert Smith, and others who have left a deep impress upon that page of Irish professional history, and we know of none remaining save Sir Dominic Corrigan and James Apjohn who can look back—as they well may—with pride upon their association with such men. Dr. Benson, who for upwards of half a century has occupied so high a position in his profession, was born in 1797, and was accordingly in his eighty-fourth year. In 1818 he obtained a scholarship in Trinity College, being at the time a resident pupil in the Richmond Hospital; in 1821 he was admitted a Licentiate, and in 1825 a Fellow of the Royal College of Surgeons, and in 1840 took the degree of M.D. in the University of Dublin. He was successively Vice-President and President of the Royal College of Surgeons. As Professor of the Practice of Medicine at the College of Surgeons, and as Physician to the City of Dublin Hospital, he had great opportunities in teaching, and he used them well. In Dublin Dr. Benson will be chiefly remembered by the untiring zeal and indefatigable efforts he bestowed in the organisation of the City of Dublin Hospital, which, first under his immediate control, and never we believe without his counsel, has made for itself a claim to be regarded as one of the very first of our Dublin Hospitals. The recognition by the administrators of the hospital of his great services to it was recently noted by us on the occasion when his portrait was placed by them in the Board Room, and it must be a satisfaction to them to feel that that recognition was not delayed until after his lamented death. We adopt every word of the following expression of feeling uttered by the *Evening Mail*:—"By his professional brethren the memory of his name will ever be cherished as of one who, throughout a long life, never faltered in the course he adopted of securing for the profession to which he belonged the honour and respect of every member of the community. He was, in short, from first to last, an ornament and a brilliant member of the medical profession. Skilful, careful, and considerate, he gained for himself and for his native city a reputation which will last far longer than we should care to count. Dublin has lost in Dr. Benson a man truthful to scrupulosity and honest and straightforward to a degree rarely ever equalled. His charity and kindliness of heart gained for him the respect and admiration of all classes of his fellow-citizens. As one of the founders of the Medical Benevolent Fund and the Night Asylum he performed a good and lasting service both to his own profession and his poorer brethren."

◆

## DR. STEEVENS' HOSPITAL AND MEDICAL COLLEGE, DUBLIN.

CHANGES in the *personnel* of this Hospital and School are on the *tapis*, and will be determined on the 5th prox., which are of much importance to the continued efficiency of the institution, and may, indeed, involve the existence of the school. Two physiciancies to the hospital are at present vacant, one by the expected resignation of Dr. Grimshaw—the recently appointed Registrar-General—the other by the death of Dr. Bookey. A consulting physiciancy is also vacant by the death of Dr. Malachi Burke, the office not having been filled since then. To this latter office it is likely that Dr. Grimshaw will be appointed *nem. dis.*

The vacant physiciancies are the subject of smart competition, and the result of the election on the 5th is looked forward to with much interest as involving the efficiency of the school, in which the new physicians will hold lectureships. For one of these appointments Dr. Reuben Harvey, Secretary of the Carmichael College, is considered, to be entitled by his rank as a practitioner and a teacher, if he will accept it, which depends upon his relation to the Carmichael College. It is considered certain that he will not disassociate himself with that school, to which he would be a most serious loss. As to the other physiciancy there is a smart contest, the favourite candidates being Drs. Warren and Tweedy. As the selection depends upon the lay Board of Governors of the hospital, it is difficult to predicate the result.

# Medical News.

**Royal College of Surgeons of England.**—The following candidates having passed the requiaed examinations for the diploma, were duly admitted Members of the College on January 19th :—

Bothamley, W. Parkinson, L.S.A.
Davis, Arthur Randall, L.S.A.
Fagg, Thomas Wilson, L.S.A.
Favell, Richard, L.S.A.
Greensill, Joseph Moore, L.S.A.
Heaven, John Cookesley, L.S.A.
Heygate, F. Nicholas, L.S.A.
Irvin, Joseph H., L.K.Q.C.P.I.
Mulroney, Thomas R., L.R.C.P.E.
Pegge, William Joseph, L.S.A.
Scale, Thomas William, L.S.A.
Todd, George Dixon
Webb, William Wilfrid, L.S.A.
Wigg, Alfred Edgar
Williams, William, L.S.A.
Wood, James

The following were admitted members on January 26th :—

Allen, Francis Edward
Armitage, Joseph
Boulter, Walter Ernest
Brooks, H. A. Grundy
Chipperfield, T. J. B., L.R.C.P.E.
Fowler, Charles H.
Haggard, Robert
Jones, W. H. Fenton
Lewis, G. Stephens, L.R.C.P.L.

Wightwick, Fallon Percy

**Society for the Relief of Widows and Orphans of Medical Men.**—The usual quarterly Court of Directors of the above Society was held on Wednesday, January 14th, in the Rooms of the Royal Medical and Chirurgical Society. The chair was taken by the President, Sir George Burrows, Bart., M.D. One new member was elected, two sent in their resignation, and the death of one was reported. Grants amounting to £1,284 were made to fifty-nine widows, fourteen orphans, and three orphans on the Copeland Fund. Fresh applications were received on behalf of one widow and two orphans. A legacy of £500 from the executors of Miss Hurst was announced by the treasurer. The expenses of the quarter were £56 12s. On the motion of Mr. Steet, it was resolved to propose to the next annual meeting an alteration in the bye-laws, to extend and define more certainly the area of the operations of the Society, by making are medical practitioners residing within a twenty-mile radius of Charing Cross eligible to become members.

**Liverpool Medical Institution.**—At the annual meeting, held January 13th, the following honorary officers and Members of Council were elected or re-elected :—*President*—Reginald Harrison, Esq. *Vice-Presidents*—John Newton, Chauncy Puzey, R. Caton, M.D., E. H. Dickinson, M.D. *Treasurer*—W. Macfie Campbell, M.D. *General Secretary*

—Rushton Parker, M.B., B.S. *Secretary to Ordinary Meetings*—Edgar A. Browne. *Librarian*—J. M. Hawie, M.B. *Other Members of Council*—A. Bernard, M.B., A. Davidson, M.A., M.D., A. F. ◆

## NOTICES TO CORRESPONDENTS.

Mr. **Rushton Parker** will find the subject of his communication in another column.

**Charity Voting Reform.**—A correspondent writes: "I am delighted to find the charity voting scandal is getting some hard knocks in the *Medical Press;* the system deserves all the exposure and condemnation you can bring to bear upon it; and I hope you will not give it up until—as has resulted in your fearless exposures of other abuses in the press—such a flagrant injustice is entirely abolished, at least from our medical charities." Whilst thanking our correspondent for his appreciative note, we can assure him that we shall recur to the subject from time to time as opportunity offers, until the much-desired consummation of which he speaks is *un fait accompli.*

**Dr. Crean**, Ballyhaunis.—We know something more of the truth of the matter than appears in the report. We have, therefore, not been able to see that the intervention of a colleague under the circumstances is "a grave ethical dereliction," though perhaps it would have been better left undone. Being aware of the facts, we cannot champion the cause of the accused, nor do we deem the intervention of the accuser inexcusable. We think silence the fairest policy to both.

**An Amateur.**—Thymol is soluble only in cold water in the proportion of 1 in 1,200 parts; in chloroform or olive-oil (warm) it is soluble in equal parts, *i.e.*, 1 part thymol in same quantity of chloroform or warm oil.

**Hunterian Society.**—This (Wednesday) evening, at 8 o'clock. Dr. Braxton Hicks, "On Obliquity of the Pregnant Uterus."—Mr. Clement Lucas will show a Case of Aneurism by Anastomosis of half the Face.

### DUAL APPOINTMENTS.

*To the Editor of the* Medical Press and Circular.

Sir,—Kindly say, do the Local Government Board prevent workhouse, as well as dispensary medical officers, holding at the same time the position of coroner? Also is the property qualification not enforced, as I know instances in which men have been elected to the coronership who possessed no property qualification apparently?

Yours, &c.,

Medicus.

[The Local Government Board has refused to sanction the appointment of a coroner to a dispensary, and probably would have the same objection to the holding of a workhouse with a coronership; but we do not know that this latter case has ever arisen. We do not think that a Poor-law medical officer who might be appointed coroner would or could legally be removed from his Poor-law appointment unless the duties of the coronership were found to clash with his Poor-law functions. (2) Candidates for coronership *must*, undar 13th sec., 9 & 10 Vic., cap. 37 ("Irish Medical Directory," page 526), deliver a statement of his property qualification to the sheriff. An opposing candidate may call on the sheriff to administer the qualifying oath ("Directory," page 531). Except by the administration of this oath, the qualification is not usually enforced.—Ed.]

**Royal Institution.**—Thursday, at 3 p.m., Professor Dewar, "On Chemical Progress."

**Dr. Alford** is thanked.

**Physiology for Boys.**—Kindly say what work on *elementary* Physiology would be the best to put into the hands of a schoolboy about 11 years of age?—Mapother's "Animal Physiology," Glasgow School Series. Longmans. 1s.

### COCKING'S POROPLASTIC JACKETS AND SPLINTS.

*To the Editor of the* Medical Press and Circular.

Sir,—In No. 2,125 of your journal a letter emanoting from Mr. J. T. Cocking is inserted, wherein he evidently seeks to infer that I wilfully pirated his poroplastic jackets.

I must request the favour of your giving equal publicity to my emphatic denial of such indirect aspersion, which is without the slightest foundation in fact, as will be seen by attentively perusing the apology signed by me appearing in the same journal.

At the time of my inadvertently infringing Mr. Cocking's patent, I, in common with many others, was totally ignorant that any such patent existed.

Of this fact Mr. Cocking was, and is, fully cognisant; and I cannot help feeling that he is adopting a most unjustifiable course in seeking to indirectly represent me as a pirate of patent rights, of which, through his own negligence, I was entirely ignorant, as neither in his advertisements, invoices, or otherwise, had he thought fit to announce that any such patent existed.

Indeed after the very ample compensation and apology which I consented to make, I can only regard it as an ungenerous attempt to obtain notoriety at the expense of, Sir,

Your very obedient servant,

Charles Strudwick.

57 Upper Marylebone Street,
London, W.

### THE AUDIPHONE AND DENTIPHONE.

*To the Editor of the* Medical Press and Circular.

Sir,—We beg to inform you that we have just received from the United States some specimens of the *Audiphone* and *Dentiphone*, both of which, as you already know, have attracted considerable attention as a help for the very deaf. As these instruments may be of considerable interest to medical men, we beg to say that we shall be pleased to show them to any who desire to examine and test them, and that they may bring any patients to try them at our office here if they like. We have none for sale, but have brought these over as a matter of curiosity.

Yours, &c.,

S. M. Burroughs & Co.

8 Snow Hill, London, E.C.

### TRAFFIC IN PSEUDO-CHARITY VOTES.

*To the Editor of the* Medical Press and Circular.

Sir,—The letter signed L. M. Gill, which appeared in your paper of the 21st inst., and your article headed, "Traffic in Pseudo-Charity Votes," which followed, were under the consideration of this Committee at their recent meeting.

I was requested to thank you for the undeviating support afforded in your columns, to the principles which this Association is seeking to promote, as evidenced by the article in question and previous matter.

I enclose copy of a speech made by Lord Derby at our last annual meeting.

Yours, &c.,

Fred. Warren,

Secretary of the Charity Voting Reform Association.

**The Dublin Obstetrical Society.**—Saturday, Feb. 7, at 8 o'clock, at the College of Physicians, the following communications are set down for reading: Adjourned discussion on Dr. Kidd's paper, "Erythema Uterinum, or Roseola Uterina."—Rev. Prof. Haughton, on "A Case of Phantom Tumour occurring in the Zoological Gardens of Dublin."

**Royal Institution.**—Friday, at 9 p.m., Mr. J. Marshall, "On the Proportions of the Human Figure."

### VACANCIES.

Ballycastle Union, Croagh Dispensary.—Medical Officer. Salary, £100, with fees. Election, Feb. 7.

Booth Borough Hospital.—House Surgeon. Salary, £80, with board. Applications to the Hon. Sec. on or before Jan. 31.

Bristol Royal Infirmary.—House Physician. Salary, £100, with board. Applications to the Secretary before Feb. 2.

Hungerford Union.—Medical Officer for No. 3 District. Salary, £30, with the usual extras. Applications to the Clerk of the Union before Feb. 10.

Huntingdon County Hospital.—House Surgeon. Salary, £60, with board. Applications to Mr. P. Tillard, Stukeley Hall, Huntingdon, before Feb. 6.

London Fever Hospital.—Physician and Assistant Physician. Applications, with testimonials, to the Secretary, Liverpool Road, Islington, by Feb. 7.

Middlesex Hospital.—Assistant Physician on the Staff. Applications to the Secretary-Superintendent before Feb. 7.

Roscrea Union Workhouse.—Medical Officer. Salary, £80. Election, Feb. 5.

Steevens' Hospital.—Consulting Surgeon and two Physicians. Election, Feb. 5. (See Advt.)

◆

## Births.

**Baker.**—On Jan. 22, at Kensington, prematurely, the wife of A. De Winter Baker, M.R.C.S., of Dawlish, of a daughter.

**Pletts.**—On Jan. 22, at Ryde, Isle of Wight, the wife of J. Menham Pletts, M.D., of a son.

**Stanger.**—On Jan. 20, at Hardy House, Wakefield, the wife of W. Stanger, F.R.C.S., of a son.

**Woods.**—On Jan. 19, at Killarney, the wife of Oscar T. Woods, M.D., of a daughter.

**Young.**—On Jan. 19, at Rose Bank, Bootle, near Liverpool, the wife of T. F. Young, L.K.Q.C.P., of a son.

◆

## Marriages.

**O'Connolly — Rice.**—At St. Patrick's, Cork, James O'Connolly, L.R.C.P.E., Durrus, co. Cork, to Lilla, daughter of the late Edward Rice, Esq., Cloghan, Tipperary.

◆

## Deaths.

**Benson.**—Jan. 21, suddenly, at 42 Fitzwilliam Square, Dublin, Charles Benson, M.D., aged 83 years.

**Molony.**—At Kilrush, co. Clare, Harry Molony, L.K.Q.C.P.I.

**Crawford.**—On Jan. 17, at Norton Terrace, Longsight Road, Manchester, James Crawford, M.D.

**Eddowes.**—On Jan. 17, at Sandymount, William Eddowes, M.R.C.S.E., Surgeon-Major, 35th Bengal Native Infantry, aged 43.

**Gill.**—On Jan. 9, at Kandy, Ceylon, George T. Gill, L.R.C.P.Ed., Assistant Colonial Surgeon.

**Seaton.**—On Jan. 21, at the residence of his son-in-law, 48 Ladbroke Grove, W., Edward C. Seaton, M.D., F.R.C.P., of 14 Gordon Street, Gordon Square, late Medical Officer to the Local Government Board, and formerly of the Medical Department of the Privy Council, in his 65th year.

## LARYNGISMUS STRIDULUS.

### By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children.

*Synonyms.*—Laryngismus Stridulus (Dr. Good)—Spasm of the Glottis, Crowing Inspiration or Spasmodic Croup—Child Crowing (Marshall Hall)—Spasmodic or Thymic Asthma of Children (German writers)—Internal Convulsions—Convulsions Interne (Trousseau, Rilliett and Barthez).

*Nature, definition, and symptoms.*—

*Causes.*—Predisposing and Exciting—Cases in Illustration—General Course and Termination—Three Modes of Death, 1 from Asphyxia, 2 from Congestion of the Brain and Effusion, 3 from Exhaustion.

*Pathology.*—A Purely Neurosal Affection of the Par Vagum or its Branches propagating an Irritation to the Muscles of the Larynx and throwing them into Spasm.

*Diagnosis.*—From Croup and Whooping-Cough.

*Prognosis.*—Favourable in Mild Cases where the Health is Good—Unfavourable in Severe Cases.

*Treatment.*—Removal of Exciting Causes—Mild Aperients—Bromide of Potassium—Attention to Diet and General Health.

THIS affection is recognised by a peculiar crowing noise which takes place during inspiration. It is so characteristic that when once heard it cannot be forgotten. It arises from spasmodic narrowing, or temporary closure of the glottis and larynx. It is a form of internal convulsion—a clonic spasm of some of the respiratory muscles. As a rule the general health is below a right standard, and the child is restless and out of sorts before the seizure happens. The disease is frequently associated with general debility, atrophy, or convulsions.

It is not uncommon for slight wheezing and catarrh to precede the development of the symptoms for some days, but it is not usually attended by cough.

Males are more subject to the disease than females. "Out of my fifteen cases, eleven were boys, so that it seems as if the larynx of male children begins even in the very earliest youth to distinguish itself in form, or at least in physiological activity, from that of female children." (*a*)

*Symptoms.*—When a child is seized with a severe attack he struggles violently, and fights with his hands clenched as if about to suffer instant suffocation; the face is livid and congested, the eyes are staring and suffused, the cervical veins are distended, the head is thrown back against the spine, and the whole body is in tremulous agitation. After about a minute or two, and some ineffectual efforts to breathe, the spasm becomes relaxed, and air passes down the larynx with a shrill crowing sound, an indication that all immediate danger has departed. The child now cries and looks terrified, and then generally falls asleep. In exceptional cases the fæces and urine may be passed involuntarily, but I believe this to be rare.

During the seizure, when the muscular struggling is at its height, the thumb may be noticed tightly bent into the palms of the hands, and the toes turned inwards and towards the soles of the feet. The wrists and ankles are similarly flexed inwards.

It should be remembered that all cases are not equally severe, nor equally frequent. Some are milder than others, the intervals are longer, and the spasms less pronounced; the child has a mild attack of catching in the breath, with slight and occasional crowing at long intervals, and then perhaps it passes off altogether if the general health improve; but if not, the spasms may gradually increase in frequency, and several attacks occur during the day. The spasms, which begin slightly in the laryngeal muscles, may become more and more severe, and in some instances terminate in general convulsions and death. Under any circumstances the seizures leave the child exhausted and drowsy, especially if they are frequent. The attacks often come on in the night, or when the child wakes out of sleep, or attempts to take food or drink.

When the bowels are disordered or there are worms in the intestinal canal, some children are liable to a loud ringing cough, of a purely nervous character, which alarms parents. With it there is excited pulse, and flushed face,

---

(*a*) Vogel on "Diseases of Children," 1874, p. 274.

but all these symptoms disappear when an active aperient is given, and the source of irritation is removed.

The duration of the disorder is uncertain. In some instances it lasts during the continuance of dentition, and passes away when the teeth have appeared; in other instances it slowly or suddenly grows worse, and ends in convulsions or asphyxia. If the disorder recur from time to time, it is seldom fatal. Spasm of the glottis has been often assigned as a cause of sudden death among infants and young children, which could not be otherwise explained. Dr. Churchill says, "I confess that I am inclined to believe that many of the deaths attributed to the nurse or mother overlaying the child, are, in truth, cases of sudden death from spasm of the glottis." (*a*)

*Causes.*—These are predisposing and exciting. Among the former are infancy and the strumous diathesis; among the latter teething and worms in the intestinal canal. Enlargement of the bronchial and mediastinal glands has been also enumerated as a cause of the affection by pressing on the inferior recurrent laryngeal nerve. "Laryngismus has boen attributed to enlargement of the thymus, but this view is not now entertained, one very good reason being that post-mortem examinations show that in many instances there is no enlargement of the organ. Moreover in cases where a large thymus has been found, there has been no laryngismus." (*b*) Further than this the disease is rare in young infants, where the thymus gland is largest. "M. Herard examined the thymus gland in six children who died of internal convulsions, and in sixty who died of other affections, and was not able to discover in its condition any causative relation to this disease. Indeed, cases have been reported in which the thymus had undergone more than its usual atrophy at the time when the convulsion occurred (Hasse)." (*c*) Though enlargement of the lymphatic glands in the thorax are constantly present without causing the disease. I cannot avoid the conclusion that there is some connection between the peculiar shrill squeaking cough when the bronchial glands are enlarged, and laryngismus stridulus. The disease is more frequent in damp and in moist situations than where the air is pure and dry. It is far oftener observed in towns than in healthy country districts. It is also said to be sometimes hereditary, occurring among families of nervous excitable persons. I have myself known three children of the same family who were affected with spasm of the glottis. "There are families in which all the children suffer more or less from it, and *Powell* even relates an instance where, out of thirteen children, brought up by the same parents, only one escaped the disease." (*d*)

As to the period of life when the disease is most common, we may mention that of infancy, and about the seventh month, when there is disturbance in dentition. After the age of three years it is much less frequent. "In 31 out of 37 cases, of which I have preserved a record, the symptoms manifested themselves between the ages of 6 months and 2 years, or just at that time when the process of dentition is going on with the greatest activity." (*e*) "Of 226 cases which have come under my own notice, 174 were in the first year of life, and the remaining 52 between the second and third years; and the relative proportion of the sexes was 150 boys to 76 girls. In both parents and children there was very frequent evidence of rickets." (*f*)

Most observers agree that laryngismus stridulus is not uncommon in cases of chronic hydrocephalus, and this has been pointed out by West, Elsässer, Vogel, and many others. (*a*) Where the nervous system is excited or exhausted it is likewise observed. I have known attacks to occur so often as to convince me that this is by no means an uncommon cause. Fright, alarm, emotion, anger, loud noises, &c., are all to be enumerated as excitants of the seizure.

The researches of Dr. Marshall Hall elaborately explain how the disease may originate through irritation of some of the cranial and spinal nerves. "Spasm of the glottis is an excitation of the true spinal or excito-motory system. It *originates* in

A. The *trifacial nerve*, in teething.
B. The *pneumogastric*, in over or improperly-fed infants.
C. The *spinal nerves*, in constipation, intestinal disorder, or catharsis.

These act through the medium of—

2. The *spinal marrow*, and—
3. A. The *inferior or recurrent laryngeal*, the constrictor of the larynx.
B. The *intercostals* and *diaphragmatic*, the motors of respiration."

*(To be continued.)*

◆

## ON THE COMPULSORY NOTIFICATION AND REGISTRATION OF INFECTIOUS DISEASES. (*b*)

By JOHN WILLIAM MOORE, M.D., M.Ch., Dub., F.K.Q.C.P.

Physician to the Meath Hospital and to Cork Street (Fever) Hospital, Dublin; Lecturer on Practice of Medicine in the Carmichael College of Medicine and Surgery; Ex-Scholar and Diplomate in State Medicine, Trinity College, Dublin.

MANY years have passed since the late Dr. Henry W. Rumsey, of Cheltenham, one of the most distinguished of the founders of State Medicine, wrote the following words:—"There are literally no published records of the cases of sickness attended at the cost of the community. The sanitary state of the people is, therefore, inferred solely from the number of deaths—that is, from only one of the results of sickness—no public account being taken of the number and duration of the attacks which shorten the effective life-time of the population." He continued: "Facts are accumulating to prove that the mere number of deaths occurring in any locality bears no constant or even approximate ratio to the real amount of unhealthiness existing there. As a necessary result of improvements in domestic management and medical treatment, and owing to the removal or absence of those more virulent agents of destruction which prematurely sever the threads of life, its duration has been lengthened in our great cities, but at the same time the sickly and infirm period of existence has been prolonged, probably in a greater degree than even life itself. Chronic diseases, or, at least, functional disorders, have increased, vital force is lowered, man's work is arrested, his duties are unperformed, his objects fail, though he still lives. Weakly, diseased children are now mercifully helped, as they never were in olden time, to grow up into weakly, ailing adults, whose children inherit their unsoundness. Is this true sanitary progress? Does it deserve the ostentatious parade of a decreasing death-rate?"

When these eloquent words were penned, only a few far-sighted thinkers like Rumsey, Acland, Farr, and Stokes, had turned their attention to the registration of disease; and in this connection I would particularly allude to a thoughtful paper by Dr. Arthur Ransome "On the Need of Combined Medical Observation," which was published in the *Brit. Med. Journ.* of October 8, 1864. At the present day, however, it seems to be generally acknowledged

(*b*) Read before the Dublin Branch of the British Medical Association, at the Annual Meeting, on Thursday, January 29, 1880.

that statistics of deaths, although founded on a more or less complete system of registration, are to a large extent wanting in precision and in scientific value. But, nevertheless, the advantages which have ever resulted from an approximative knowledge of the variations in the death-rate from season to season, and of the probable causes of the same, more than counterbalance the defects of the registration system as at present organised. How far these shortcomings may be obviated is a question which has yet to be answered. But even granting that our registration system may be perfected, we may well ask whether there is not a further step to be taken—whether it would not be politic to extend the principle of registration, which has hitherto been restricted to *mortality*, to *disease* also. Nor should it be forgotten that even in the United Kingdom the registration of epizootic infectious diseases is already in force, a fact which cannot but be regarded as a strong argument in support of the necessity for, and the practicability of, a registration of infectious diseases affecting mankind.

Viewed as a problem in political economy, there can be no doubt regarding the paramount importance of ascertaining the actual sanitary state of a population at any given time.

Death is one thing—disease is essentially another. An epidemic of influenza or of rötheln, characterised perhaps by a very low percentage of mortality, may, notwithstanding, by its mere excessive prevalence, paralyse a community to a far greater degree than a very fatal, yet limited, outbreak of cholera. Sir Thomas Watson states, (a) on the authority of the Transactions of the College of Physicians, that on the 2nd of May, 1782, Admiral Kempenfelt sailed from Spithead with a squadron, of which the "Goliath" was one. The crew of that vessel were attacked with influenza—"la grippe," as the French expressively term it—on the 29th of May, and the crews of the other vessels were at different times affected, so many of the men being rendered incapable of duty by this prevailing sickness that the whole squadron was obliged to return into port within a few days. Mercatus asserts that before the beginning of autumn, in the year 1557, influenza attacked all parts of Spain *at once*, so that the greatest part of the population in that kingdom were seized with the disease almost on the same day. At St. Petersburg, in the epidemic of 1782, Maertens says that on a cold night the thermometer rose 30° Fahr., and next morning 40,000 people were taken ill with the influenza. We can readily imagine what serious consequences might possibly attend outbreaks of sickness such as these, although they would not necessarily leave their mark upon the statistics of mortality.

Again, under ordinary circumstances the prevalence, or otherwise, of an endemic disease stands in no direct relation to the published returns of mortality attributed to it. The argument in favour of registration of disease deducible from this fact applies *à fortiori* in the instance of an epidemic, where the ratio of cases to deaths is of a most varying and uncertain character.

Difficulties, no doubt, stand in the way of carrying out an effective system of disease registration, but they are not insurmountable, and the fact that several European governments have long since inaugurated and prosecuted such a system should encourage us in essaying to follow their example. In the vanguard of progress in this direction the Scandinavian nations occupy the place of honour.

For many years back the College of Health at Stockholm has received monthly and annual reports of the sanitary state of the country, including an account of the prevailing endemic and epidemic diseases, from a corps of officially appointed medical men, styled provincial and district physicians, subsidised by the State. The monthly reports furnished by these physicians are published from time to time in the Swedish medical periodical *Hygeia*, while the annual returns are compiled and arranged by an official whom we may call the Swedish Registrar-General, and are finally presented to the king in the form of a blue-book, or volume of official reports and tables.

A similar organisation exists in both Norway and Denmark—so far, at all events, as relates to the registration of epidemic diseases. In the "Weekly Report of Diseases, Deaths, and Births in Copenhagen," communicated by Dr. P. A. Schleisner, medical officer of health, and published by authority of the Municipal Council, the first table gives the cases of epidemic and contagious (infectious) diseases reported to him by the medical men practising in the Danish capital. The notification of these diseases is compulsory.

Our American cousins have also adopted a system of registration of disease in some of their large cities, and the authorities of some of the Swiss cantons are following their example. (a)

Before I proceed to sketch the progress already made in establishing a registration of disease in our own country, it may not be amiss to state that the powerful Association of which we—the Dublin Branch—form a by no means unimportant integral part, have, for fifteen years at least, consistently and constantly promoted the registration of disease. Dr. Grimshaw, the present able Registrar-General for Ireland, stated, in his recent address to the section of Public Medicine at the annual meeting of the British Medical Association in Cork, (b) that at the Leamington meeting of the Association, in 1865, a committee was appointed to promote the registration of disease. This committee attempted to establish a voluntary registration of sickness in public practice, but the attempt ultimately failed. Unsuccesful, but not discouraged, the committee never ceased urging upon the Government the importance of the systematic registration of disease, and suggested it as a fit subject for the consideration of the Royal Sanitary Commissioners. A national system of registration of disease in general unfortunately still remains a thing of the future.

There is, however, one class of affections which, in the interest of the community, should be registered with as little delay as possible—at least in all large towns. I allude to epidemic infectious diseases. Instances are constantly coming under the notice of hospital physicians in which scarlatina, small-pox, measles, and fever have spread far and wide, because the first case of illness, either through wanton neglect or ignorance, was not isolated in due time. Some weeks ago several cases of scarlatina were admitted into Cork Street Hospital from a tenement house in which a child died of this disease and was waked. No medical man had been called in to see the patient, nor was any report made to the sanitary authorities until other children in the house had been attacked. At least two lives were lost in this instance, which is only one out of many which might be adduced.

Two things would seem to be necessary in the case of outbreaks of epidemic infectious diseases—first, the immediate compulsory notification of such outbreaks to the sanitary authorities; secondly, the early registration of all cases of these affections, and the publication of the tabulated results at frequent intervals by the General Registration Offices of each division of the United Kingdom. Towards securing the second object but little has yet been done. As regards the notification of infectious disease, on the contrary, Parliamentary powers have already been sought and obtained by fourteen towns in England and Scotland—viz., Huddersfield, Bolton, Greenock, Burton-on-Trent, Nottingham, Jarrow, Llandudno, Warrington, Blackpool, Norwich, Edinburgh, Rotherham, Leicester, Blackburn, and Derby.

Mr. Ernest Hart, the chairman of the Parliamentary Bills Committe of this Association, in an admirable report "On the Recent Progress of Legislation with regard to the Notification to Sanitary Authorities of the Occurrence of Cases of Infectious Disease," (*a*) gives a synopsis of the clauses in the local Acts of Parliament relating to such notification in the towns mentioned above. From this synopsis it appears that by the Bolton Act, and by the Jarrow, Llandudno, Warrington, Blackpool, Rotherham, Leicester, and Derby Acts, founded more or less upon it, the duty of making this notification is imposed alike on the occupier and on the medical attendant—the *prima facie* duty of complying with the statute is cast upon the occupier, and a fee of half-a-crown in most cases, but only one shilling in the case of Jarrow, is payable to the medical men for his certificate. The Burton-on-Trent and Blackburn Acts require the occupier to give notice only when a medical man is not called in, and, as Mr. Hart says, thus obviously offer a premium to delay in seeking for medical advice in cases of infectious disease. The Edinburgh Act, again, by imposing no duty at all upon the occupier, is likely to lead to the employment of quacks and unregistered practitioners to even a greater extent than at present. At Greenock the notification, to be given by the householder to the sanitary inspector within twenty-four hours, is required only on its being certified by the medical officer of health that "epidemic, contagious, or infectious disease" exists within the limits of the town. At Nottingham and Norwich, as well as, to a less extent, at Huddersfield, the plan proposed by the committee of this Association has been adopted. "By the Nottingham plan," Mr. Hart observes, "the medical attendant is required to fill up, sign, and deliver to the occupier or person having the management or control of the building, or, in case such person is suffering from infectious disease, to the person in charge of the patient, a certificate, which must be forthwith delivered *by the person to whom it is given* by the medical practitioner, at the Town Hall, to a clerk or servant of the corporation. If no medical attendant be called in, the occupier or other person is, so soon as he becomes aware of the existence of the disease, to give notice to the corporation forthwith. In the event of the sufferer not being a member of the occupier's family, the head of the family (resident in such building) to which the patient belongs, or, if there be no head, the patient himself (unless prevented by such disease, or by youth) is to give notice of the existence of the disease to the occupier or other person as above."

(a) See *British Medical Journal*, December 27, 1879. Page 1030.

(b) The Public Work of the British Medical Association. Dublin; Fannin & Co. 1879. Page 10, *et seq.*

In the Report of the Committee on the Registration of Disease adopted by the British Medical Association in 1876, the position of the medical profession in regard to the notification of infectious diseases is thus ably summed up :—"The authoritative declaration of the nature of the disease must necessarily come, in the first instance, from the medical attendant. On the other hand, to be obliged to furnish information to a public official with regard to sickness occurring in a family might reasonably be resented by the medical profession. It would be regarded by many not merely as an unnecessary addition to their work, but as an inquisitorial test of the extent of their practice, and as leading to a breach of professional confidence that might cause annoyance both to doctor and patient. . . . . .
No such objections apply to the proposal to make the householder responsible for the declaration of the presence in his house of diseases likely to be injurious to the community."

It is sincerely to be hoped that an effort will be made, without delay, to secure for Dublin the advantages of some such system of notification and registration of infectious diseases. Any system of the kind should be carried out not merely within the municipal boundary, the limits of which are now more than ever artificial, but also in the adjacent townships. For registration purposes, the Dublin Registration District would seem to be a suitable area for the application of an Act of Parliament. I feel sure that the present Registrar-General for Ireland, Dr. Grimshaw, would gladly afford every facility for the organisation of an efficient system of disease registration once the necessary Parliamentary powers have been obtained.

As to the nature and scope of those powers, I cannot do better than conclude this brief *résumé* with a model clause for an Act of Parliament, drafted by Mr. Ernest Hart, and based partly upon the Nottingham Act, already referred to, and partly upon general experience of the working of the system of disease registration :—

"In order to secure that due notice be given to the sanitary authority of any inmate of any building used for human habitation in the district who is suffering from small-pox ; cholera ; typhus, typhoid, scarlet, puerperal, or relapsing fever ; diphtheria, measles, or erysipelas, the following provision shall have effect ; that is to say :—

"1. If any such inmate be suffering from any such disease, and no medical practitioner be attending on, or have been called in to visit, such inmate, the occupier or other person having the management or control of such building, or, if such occupier or other person be prevented by disease or otherwise, the person in charge of such inmate shall, so soon as he shall become aware of the existence in any such inmate of any such disease, forthwith cause notice thereof to be given to the sanitary authority at their office.

"2. If the person suffering from the disease be not a member of the family of such occupier or person, the head of the family (resident in such building) to which such inmate belongs, or, if there be no such head, then such inmate (unless prevented by reason of such disease or of youth) shall, on becoming aware of the existence in such inmate or in his own person, as the case may be, of such disease, forthwith give notice thereof to such occupier or person.

"3. Every medical practitioner attending on or called in to visit such inmate shall, on becoming aware that such inmate is suffering from any such disease as aforesaid, forthwith fill up, sign, and deliver to the occupier or person having the management or control of the building, or, in case such person is suffering from such disease, to the person in charge of such inmate, a certificate stating, according to the forms prescribed and supplied to him by the Corporation, the name of such inmate, the situation of such building, and the name of such occupier or person, and the nature of the disease from which such inmate is suffering.

"4. The person to whom such certificate shall be given by the medical practitioner shall forthwith deliver the same, or cause the same to be delivered, at the office of the sanitary authoritiy [to a clerk or servant of the authorityin attendance there].

"5. The sanitary authority shall supply gratuitously to every registered medical practitioner resident or practising in the district forms for the certificate by such medical practitioner of the particulars hereinbefore mentioned of cases of infectious disease attended by him ; and the authority shall pay to every medical practitioner who shall, in pursuance of this section, duly give any such certificate, a fee of two shillings and sixpence in respect of the same ; provided that more than one fee shall not become payable under this section within an interval of thirty days to the same medical practitioner, for certificates given by him in respect of the same disease occuring in the same building.

["6. The sanitary authority may from time to time, by resolution, order that, subject to the approval of the Local Government Board, any acute infectious disease, other than those above mentioned, shall be deemed to be within and subject to the provisions of this section.]

"7. Any such order of the sanitary authority may be permanent or temporary only ; and, if temporary, the period during which it is to continue in force shall be specified therein ; and when the Local Government Board have approved of any such order, the sanitary authority shall give public notice of the order by causing a copy thereof to be affixed to the principal door of every church and chapel in the district to which notices are usually affixed, and by publishing the same by adver-

---

(*a*) See *Brit. Med. Journal*, Nov. 22, 1879, p. 830.

tisement in some one or more of the local newspapers circulated in the district; and, after such public notice has been given, the provisions of this section shall, so long as the order continues in force, apply to the acute infectious disease specified therein, in like manner in all respects as if the disease were mentioned in this section."

With regard to the preamble to this model clause, it would seem desirable that the infectious diseases should in each case be scheduled, and that the Act should give power to the *Privy Council* to alter or add to the list of such diseases. In sub-clause 3 it would be well to insert after the word "certificate" the words "according to the schedule to this Act." In sub-clause 4, and in the proposed certificate hereto appended, the words "to a clerk or servant of the authority in attendanee there" might very well be omitted. Sub-clause 6 should also be omitted, for it gives to the sanitary authority a discretion in the matter which is not expedient. For the same reason subclause 7 would require alteration.

I append also a model form of the certificate to be given by medical attendant to the occupier for transmission by the latter to the sanitary authority.

"—— Improvement Act, —— Section ——.

"Pursuant to the above-mentioned Act, I hereby certify and declare that, in my opinion, the undermentioned person is suffering from a disease within the terms of the said Act.

"Dated the day of 18 .

"(Signed) Medical Practitioner Duly Registered.

"1. Name of person suffering from the disease.
"2. Situation of the building wherein such person is.
"3. Name of occupier or other person having the management or control of the building.
"4. Nature of the disease.

"To Mr. of

"Take notice that this certificate must be forthwith delivered at the office of the sanitary authority [to the clerk or servant of the authority in attendance there], under a penalty not exceeding pounds."

For the registration of infectious diseases a somewhat different machinery will be required. It does not appear just or expedient to inflict upon the relatives of the persons attacked with illness the duty of *registering* the disease. For my own part I do not see why medical practitioners could not as easily fill up disease certificates as they do death certificates, blank forms and addressed envelopes to the General Registration Office being supplied them for the purpose. Intentionally I say "addressed envelopes to the General Registration Office," for medical men might reasonably object to the extent of their practice being scrutinised by the deputy registrars throughout the city, whereas no reasonable exception could be taken to the confidential and direct transmission of the requisite information to the Registrar-General, either at stated periods, or as the cases of disease came under observation.

◆

## THE POSITION OF IRISH MEDICAL OFFICERS OF HEALTH. (a)

### By JOHN H. CHAPMAN.

The position of the Irish Medical Officers of Health is peculiar and unsatisfactory, and, therefore, worthy of the best consideration of this Society.

By the 11th Section of "the Public Health (Ireland) Act, 1878," every medical officer of a dispensary district is *compulsorily* constituted a sanitary officer for his district under the title of "medical officer of health."

The same section of the Act provides that the Local Government Board "shall assign to the medical officers of health, and to the other sanitary officers, if any, their *respective* duties and functions in the discovery, or inspection, or removal of nuisances, in the supply of pure water, in the making or repairing of sewers and drains, or in generally aiding the administration of the sanitary laws within the district."

The words, "if any," in this section, bear the inference that there might possibly be no other sanitary officer for the district than the medical officer of health, in which case that officer might possibly be considered to stand charged with the responsibility of performing all the sanitary duties of the district; but be this as it may, the Local Government Board have, by their sanitary orders (which here date 8th August, 1879) assigned to the several sanitary officers their respective duties and functions, those of the medical officers of health being as follows, viz.:—

"Every medical officer of health who shall have been apprised officially by the sanitary sub-officer, or shall otherwise become cognisant of any matter demanding his attention as aforesaid, shall, as soon as practicable, visit the place, and if, after due inspection, he finds such matter to involve danger to public health, he shall report thereon to the sanitary authority, in the Form (B) in the said Schedule B, showing the source from which he received the information, and the date thereof, and the date of his visit of inspection; he shall also give a sufficient description of the nature of the case, and the remedy which he recommends to be adopted, and shall preserve a duplicate of every such report.

"Every medical officer of health shall inform himself, as far as practicable, respecting all influences affecting or threatening to affect injuriously the public health within the district in his charge, and shall from time to time, as occasion may require, report on the subject to the sanitary authority, and recommend the measures which, in his opinion, should be adopted for the protection or improvement of the public health in such district.

"Every medical officer of health, and sanitary subofficer of the union shall attend meetings of the sanitary authority, whenever required to do so, and shall assist in all proceedings in which his assistance may be required.

"Every medical officer of health, and every other officer appointed under this order, shall, in matters not specifically provided for in this order, observe and execute the instructions of the Local Government Board and all the lawful orders and directions of the sanitary authority applicable to his office."

The word "respective," as applied to the duties of the medical officers of health, has been very freely interpreted, and although a medical officer of health cannot legitimately be called upon to perform duties inconsistent with the proper functions of the profession, yet the above quoted orders are by sanitary authorities held to include duties which are not professional, and not legitimately connected with the office.

It will be observed that one of the duties of the medical officer of health is to visit, inspect, and report on any matter *demanding* (in the opinion of the Inspector of Nuisances) *his attention*. This power of discrimination has been much abused, and too frequently has the attention of medical officers of health been demanded in cases which the Inspector of Nuisances alone was capable of dealing with; and concerning which, it was quite unnecessary to call upon the medical officer of health to examine and report. This I believe to be the experience of nearly every medical officer of health. In disputed cases—be the nuisance ever so palpable—I admit that the services of the medical officer of health are demanded, but in cases which can be abated without calling upon him to interfere, I cannot think it right that he should be unnecessarily troubled.

It is also a duty of the medical officer of health to assist in all proceedings in which his assistance may be required; but surely his assistance cannot be held to be required in cases which can be disposed of satisfactorily without it.

Instances are not wanting to show that sanitary authorities, executive sanitary officers, and inspectors of nuisances are endeavouring to relieve themselves of the trouble and responsibility of making inspections for the purpose of seeing that the orders of the sanitary board have been carried out, with reference to the nuisances reported by the medical officer of health, and to cast upon the medical officer of health the duty of making re-inspections as often as may be desired, until the nuisance reported by him has been abated; thus, in fact, putting it upon him to discharge one of the most important and time-occupying duties of the inspector of nuisances. Is it to be considered that the services of a medical officer of health are "*required*" or "*demanded*" in cases which could, and should, be finally dealt with exclusively by the other sanitary officers?

---

(a) A paper read before the Society of Metropolitan Medical Officers of Health, Dublin, on January 14th, 1880.

Owing to the designations of the other sanitary officers, viz., "executive sanitary officer" and "sanitary sub-officer," terms which are utterly unintelligible to the general public, the vast majority of complaints as to nuisances are made, in the first instance, to the medical officer of health, who thereupon is required to inspect and report upon very numerous matters which could easily be disposed of by the inspector of nuisances; this is, I consider, a great and unnecessary hardship.

There are no such designations in the Act of Parliament as "executive sanitary officer," or "sanitary sub-officer." Throughout the entire Act, and I believe, without a single exception, these officials are referred to as "the clerk to the sanitary authority," and the "inspector of nuisances." Why should not these intelligible designations be used? or why should the medical officers of health have to suffer so unnecessarily because they are not?

Depend upon it the law will be evaded in consequence of these unsatisfactory designations of officials not corresponding with those contained in the Act itself, and because the sanitary orders do not state that they are meant to be the same persons as are referred to in the Act.

In urban districts the executive sanitary officer might, perhaps, be better designated as the secretary to the sanitary authority, and to him all complaints should, in the first instance, be made; the services of the medical officers of health being capable of being called into requisition only by him, unless in cases of alleged neglect on the part of the other officials.

This arrangement would meet the legal requirements, as well as those of the public, and be no more than reasonable as regards the medical officers of health. I do not for a moment suggest that the medical officer of health should not be required to report on sanitary defects which come under his own immediate cognisance; on the contrary, I consider he should, if he is fairly paid for so doing, but not otherwise.

In estimating the salaries of the medical officers of health no allowance seems to have been made for the fact that he is the only person who can exercise any supervision over the inspector of nuisances. The chief object of almost every sanitary authority in Ireland appears to be to pay as little as possible to the medical officers of health, and to take care that as little sanitary work as possible, which entails expenditure out of the rates, shall be done.

At first, indeed, the sanitary authorities appear, merely for the sake of imposing as much work as possible on the medical sanitary officers under the Act of 1874, to have directed that they should be kept busy, but it was soon found that to do this incurred expenditure out of the rates; and latterly it seems that the medical officers of health have been left pretty much to work or not, as they pleased: and as zeal on their part was not recognised substantially, they could not avoid seeing that the less they did the better would they please the sanitary authorities.

Were the medical officers of health reasonably remunerated for the services they are or may be called upon to give, I would not think of raising these questions. But they have not been reasonably remunerated for the services they have given, much less for the full performance of the duties assigned to them, and it is notorious that there is not, in all Ireland, a single instance to be found where adequate remuneration has been offered to any medical officer of health for the full performance of his duties.

There are two sides to this question, and they are both equally important, tending, as they do, to one and the same issue. I would put them thus: (1) the duty of the medical officers of health to the public, and (2) the duty of the public to the medical officers of health. These are questions which, I think, are worthy of the consideration of all interested from a practical point of view, and the sooner a satisfactory understanding is arrived at, the better it will be for all parties.

It is the duty of the medical officers of health to exert themselves to the utmost of their ability to protect and improve the public health of their districts, but it is equally the duty of the public to pay fairly for such services.

On the one hand the Irish medical officers of health are not in a position to be philanthropists, whilst, on the other hand, the public, as a body, cannot be considered to be fit recipients of any unpaid-for services from them. Who reaps the benefit of the good services of the medical officers of health? Is it not the public? But who pays for the work? Ah! that is the question. It is not paid for as it should be, and consequently, with but very few exceptions indeed, it has not been thoroughly and efficiently performed. I appeal to this Society now to declare its opinion whether it is desirable that the existing state of affairs should be perpetuated, or whether, for the public benefit, the duties of the medical officers of health should be required to be efficiently discharged and adequately requited, bearing in mind that the extent and nature of the services should in each instance be taken into consideration, and that, unless such terms be offered as will be reasonably remunerative, it is utterly futile to expect satisfactory results. Look at the sanitary condition of Ireland, consider its arrangements for sanitary work, and say what is the cause of its deplorable state. I think it is this, at least, to a great extent: the medical officers of health—the only officials who are capable of effecting any material improvement—are paid but nominal salaries, though many of them have each year, for several years, given services well worthy of from ten to twenty times as much as they were paid, and yet fared no better than others who have done very little indeed. The natural lesson to be learned from this erroneous policy of the sanitary authorities is for the medical officers of health not to trouble themselves about discharging their duties. If a decided change of policy be not soon made I fear very few indeed will be found to continue to give services much beyond the value of the money they receive. This, I consider, is the practical view to take of this question.

The salaries of the medical officers of health, not only in Dublin, but throughout Ireland, should be revised and made commensurate with the work done, the time necessarily occupied, and trouble involved, each being paid according to his deserts.

In many instances the present salary does not pay for the time occupied in receiving complaints (sometimes made personally, sometimes by letter), and the necessary correspondence and explanations concerning them, without including a single inspection or report. As a matter of choice there are some who would not accept double the amount of their present salaries for the sanitary duties discharged by them, irrespective altogether of those which the sanitary authority are aware of, viz., inspection and reports.

The duties of a medical officer of health are of necessity exceedingly troublesome and onerous, and frequently not only disagreeable, but directly at variance with his interests.

Acceptance of the office should be voluntary, and where declined by the dispensary medical officer, an appointment should be made by the Local Government Board, by whom the salary should be fixed; effective supervision by independent medical officers should also be provided. Nothing short of this can possibly ensure success. The sanitary authorities (speaking generally) evince but little desire for sanitation, whilst many dispensary medical officers would prefer not to have to discharge sanitary duties under any circumstances. What, therefore, can the public expect under the existing *régime?*

The principle of fair pay for fair work should be applied to the medical officers of health as well as to all other classes of the community. It is a grave injustice that advantage should be taken of them because they are statutable officers, and consequently deprived of the option of refusal of the office. It cannot be denied that the Legislature of Great Britain and Ireland has invariably been considerate of vested interests, nor will anyone venture to state that Parliament ever intended that the interests of the dispensary medical officers should be so utterly sacrificed as they have been through the imposition upon them of public duties which have not as yet been reasonably requited, and which I regret to think never will be under the existing law. However, the medical officers of health can protect themselves to some extent by not voluntarily performing duties for which they are not to be remunerated. The authorities can only reasonably expect that the services to be rendered by them will be measured in proportion to the award; but while as far as possible guarding their own interests, the medical officers of health should be ever mindful, and very considerate also, of those of the public.

Pending the consideration of the question of payment, by the Treasury, the Local Government Board, and the sanitary authorities, I hesitate to suggest the course of action which I consider will be necessary for the medical officers of health to take for protection of their interests. However, if they are not to be very much more liberally rewarded for their services it is clear that some very decided step must be taken to free themselves of this burthen.

# Clinical Records.

## MERCER'S HOSPITAL, DUBLIN.

### Under the care of Mr. E. Stamer O'Grady.

*Excision of Knee with subsequent Amputation of Thigh —Case complicated with bad "Bed-sores."*—A weak, underfed, emaciated lad, æt. 18, who was also of feeble intellectual development, was admitted 13th March, 1879, for disease of the left knee of long standing, and associated with considerable impairment of the general health. After eight weeks constitutional or local treatment, during which the joint steadily become worse, it was excised on the 10th May, the H operation being practised. The cartilages of both the femur and tibia were considerably eroded, and in the former bone disease extended so far up into it as to necessitate a second section, as also the removal of a piece from the inside of the shaft in an obliquely longitudinal direction. The patella was taken away. By use of an Esmarch's bandage, the operation was absolutely bloodless; some slight oozing occured on its removal, but no vessel had to be tied. The parts were thoroughly dabbed with a 40-grain solution of chloride of zinc, and in dressing the wound due provision was made for drainage by means of two meshes dipped in carbolised oil, and pendent respectively from the inner and outer incisions. The limb was put up in the box-splint ordidinarily in use at the hospital for this operation. A good deal of shock, associated with sickness of stomach, supervened. Such was gradually rallied from; the patient had a good night, and next day was doing nicely. For a time, both constitutionally and locally, all appeared to progress as well as could be desired, save that eight days after the excision indications of bed-sore were observed over the sacrum. Three days later, to facilitate change of position, the box was changed for a posterior, scored with a long lateral outer splint. The slough of the bed-sore duly separated, and for a time the ulcer improved in appearance, but soon again it began to spread, and other pressure sores to form over the posterior and superior spine of ilium. The integument covering the vertebral projections and angles of scapulæ also got red and chafed; every effort made medicinally or by bed arrangement proved nugatory to prevent this pressure sore formation, notwithstanding which, for a time, the general health held up and even improved; the operation wound, likewise, apparently continuing to progress favourably, till in a little more than five weeks the anterior and inner incisions had entirely healed, the external one being nearly so too; but there was no evidence of consolidation of the bone. In spite of every attention to padding and dressing, a pressure sore had formed where the lateral splint crossed the ileum; every effort was made by chambering the spot to protect it. Still further on, by constant attention to position and frequently changed dressings, some improvement had been induced in the original bed-sore, but others had formed over the tuberosities of the ischia and elsewhere. Large abscess formation had occurred up the thigh discharging above and below, and from its interior severe bleeding had on more than one occasion occurred. The suppuration increased, became very profuse, and was attended with marked degeneration of the general health. This condition in every way progressed, and the patient rapidly lost ground. He emaciated to a notable degree, and the parts about the knee became more and more disorganised. Eventually, seventy-five days after the excision, the thigh was amputated at the upper third by long anterior and short posterior flaps; a caoutchouc tube wound round the groin controlled the bleeding well; the vessels on the face of the stump were seized in hemostatic forceps, and successively secured, eleven were thus tied by carbolised cat-cut, and scarcely any blood was lost, save what came from the medullary membrane of the bone, this was free and persistent, even after being controlled by digital pressure on an intervening dossil of lint for four and a-half hours. On its removal the bleeding actively recurred. Roleaux of cat-cut (a) were substituted for the compress, and drainage-tubes having been placed *in situ,* the stump was firmly bandaged. During the twenty-four hours succeeding the operation the patient's state required the administration of two and a third grains of morphia. *In less than a fortnight the stump had thoroughly healed,* but the patient's state from the bed-sores long continued to be truly deplorable. In no position could he get a sound decubitus; a large portion of the twenty-four hours was passed on his belly. Convalescence was delayed, the knee, too, became contracted—the heel being in apposition to the notes. After this condition was remedied by the weight and pulley, such weakness of the joint and limb obtained, that for a long time it was not safe to trust the patient on crutches. All through he continued to be a capital feeder; this stood to him, improvement eventually getting started in the bed-sores, and repair slowly progressed, an infinite variety of applications being used to them throughout; gradually they all nearly healed, and ultimately, after a stay of nearly ten months in the hospital, the patient who, as is often observed in the subjects of thigh amputation, had grown very stout, was discharged to the Convalescent Home, where the healing of the bed-sores progressed favourably.

*Comminuted Fracture of both Bones of the Leg, with*

---

(a) In a former case also of excision of the knee where profuse and dangerous reactionary hæmorrhage had occurred, from a gouged out cavity in the cancellous tissue and blanched the patient, this manœuvre also proved successful, and the patient, a young woman, recovered with a capital limb. The device was first resorted to by a Continental surgeon to plug up an artery in the after amputation of the leg, the circumstances being similar to those in which Liston is said to have been driven to use a peg of wood.

*severe Contusion of Soft Parts—Integumental Lesion and threatened Gangrene.*

The patient was a carpenter, æt. 58, and the injuries were caused by a balk of timber falling on the limb, and for a time fastening it to the ground. The integuments at each side on the posterior aspect were considerably torn. The fractures were comminuted, and placed near the middle of the limb. For some days the foot and lower part of the leg remained cold and apparently bloodless, so much so that Mr. Nixon, who in Mr. O'Grady's absence kindly took charge of the earlier treatment of the case, feared amputation might be necessary. The dressing of this case involved much care and trouble. The fracture was slow to unite, but good union was obtained when the patient was discharged from the hospital, fifty-six days after the accident. There was still a great deal of brawny thickness of the limb remaining, extending half-way up the thigh, together with considerable articular effusion. The patient continued to attend as an extern, and, by steady and methodical pressure, this state of affairs daily improved. (*a*)

## OPHTHALMOLOGICAL NOTES.

Translated and Annotated by

ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S.,

Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital and Dublin Eye and Ear Infirmary.

(*Continued from page 38.*)

### *Operation for Pterygium.*

Dr. Yreau Munar (Palma, Majorca) describes in a letter of the 20th May, 1879, the following method, which has been employed by him with signal success during six years.

Firstly, he detaches the pterygium from summit to base; secondly, he folds it back in such a manner that the point touches the middle of the posterior surface of the base, fixing it in this position by means of two or three sutures. The external surface of the pterygium is thus turned towards the eye.

### *On Thrombosis of the Retinal Vessels.* (*a*)

Retinal thrombosis is, according to the author, of more frequent occurrence than is generally believed; it may result from gouty endarteritis, syphilis, rheumatism, and traumatism. It may be distinguished from embolism by the transformation of the vessels, which, in cases of thrombosis, resemble white cords, appreciable by means of the ophthalmoscope.

### *Entropium and Trichiasis. Canthoplasty and Sutures of Gaillard.—Cure.* (*a*).

We have already spoken of this process (*Annales d'Oculistique*, 1879, p. 146), and advised its non-employment on account of the hideous cicatrices caused by it. Acknowledging, however, its powerful effects, the author writes to us on this subject. "The greater number of people in France attacked by entropium and trichiasis belong to a class which troubles itself very little about the cicatrices which may be left by Gaillard's suture." "At the same time," he adds, "it is better not to have them," evidently.

### *Cataract consequent on Typhoid Fever.* (*b*)

This refers to the cases of two young girls who were attacked by cataract after typhoid fever. The author believes the cataract to have been induced by the fever, but admits that he has never met with, in any author, a parallel case.

### *Optometrical Process.*

M. Prompt has described (*c*) an experiment which, in his opinion, facilitates the measurement of the limits of distinct vision. The experiment consists in causing the patient to look at a surface divided into lengthened rectangles, alternately black and white, and to place immediately before the pupil, on a level with the eye-lashes, a pin held parallel to the long side of the rectangles. The distance between the eye and the surface observed is then varied; whenever the surface is either too near or too far from the eye, the pin stands out on the white rectangle like a black line. Within the limits of distinct vision, however, nothing is seen but the geometrical figures in question. If the pin be displaced parallel to these surfaces, though still held near the eye, the shadow projected by it will also be displaced, but in a direction contrary to that taken by the pin; thus, if the surfaces be beyond the limit of distinct vision, the shadow follows the pin, whereas if within, it moves in the contrary direction. M. Prompt has constructed an optometer conformably to these data, and suitable to the measurement of hypermetropia and myopia—perhaps of astigmatism?—by substituting a surface consisting of a series of small black and white squares.

### *Atrophy of the Optic Nerves in Erysipelas of the Face.* (*d*)

Erysipelas of the face may lead to permanent derangements of vision, sometimes one eye only being affected sometimes both. In either case, after a greater or less period of time, atrophied degeneration of the papilla has been found to result.

The author has seen two cases of this kind, and has collected from various medical works six others, which leave no doubt as to the connection between this derangement and erysipelas. Having described the cases which have fallen under his own observation, he then proceeds to analyse those which are only known to him through the observation of others, and seeks, by comparing them, to discover the cause and significance of this serious complication in erysipelas.

We learn from these comparisons that derangements of vision occurring under these circumstances are frequently followed or accompanied by atrophied degeneration of the papilla. Optic neuritis has not been noted in any of these observations.

Dr. John Buchanan, the diploma vendor of Philadelphia, is again in trouble, this time about an alleged abortion case.

---

(*a*) There was in the hospital simultaneously with the subject of the above case another fracture of the leg also similarly caused by the falling of a balk of timber; the patient, a healthy-looking male, æt. 30. In this case too a good deal of local damage to the soft parts had occurred at the time of the injury, and repair also was very slow, no union having occurred five weeks after the accident. Friction of the extremities of the fragments against one another, was now tried and the process was repeated in a fortnight. Subsequent to this repair got started and the patient was discharged with a well-united limb, seventy-nine days after the accident. In both cases the administration of moderate quantities of alcoholic stimulants during the later portion of treatment is believed to have acted very beneficially. It so happened that a third fracture of leg, also the result of direct local violence, chanced to be under treatment coincidently with these patients. Here a lad æt. 15 years, was kicked and then trampled on by a bullock, causing fracture of fibula three inches above ankle, and also fracture of internal malleolus; there was much displacement, and in this case too there was considerable contusion of soft parts, with copious blood extravasation. Repair was rapid, the patient being able to leave hospital after a stay of twenty-four days, the accident having occurred in the country two days before his admission.

## SOCIETY OF MEDICAL OFFICERS OF HEALTH.

President—JOHN SYER BRISTOWE, M.D.

AT a meeting of the Society held at 1 Adam Street, Adelphi, on Friday, January 16th, Dr. JOHN TATHAM, Medical Officer of Health for Salford, read a paper "On Certain Reforms which appear desirable in the Statistical Tables adopted in their Annual Reports by Medical Officers of Health acting for large Urban Districts," of which the following is an abstract :—

After acknowledging that the tables recommended by the Society were of value to metropolitan health officers, he pointed out that they were but sparingly adopted in the provinces. Moreover, the tables had been drawn up some five years ago, and it was now worth while considering whether these forms could not be modified so as to answer the purpose of metropolitan as well as extra-metropolitan officers of health. It is to be regretted that though the whole of England has been parcelled out into sanitary districts, the national collection of local sanitary statistics is so meagre as to be positively discreditable to the public health service, a result due to the fact that the health officers are working solely with regard to local requirements, and entirely without reference to a national statistical system. Dr. Tatham then suggested that the tables which he submitted to the Society should be referred to the same Committee which five years ago compiled the statistical forms of 1874, and at the same time he stated that the tables were the work of a friend who had had great experience in vital statistics.

The following is a summary of the information given in the tables which accompanied the paper :—

*Table A.* Gives the density and birth and death rates.

*Table B.* Gives an analysis of the mortality for a series of years. It shows the deaths of children at ages under one year, under five years, and those of persons over sixty years, and also the death-rates at those ages, and from seven zymotic diseases, the infantile mortality being measured by the number of children dying under twelve months per 1,000 births.

*Table C.* Gives the births registered in a town and in its various registration sub-districts, wards, or other statistical sub-divisions, distinguishing legitimate and illegitimate births.

*Table D.* Gives the estimated population, the births and birth-rate, the deaths and rate of mortality per 1,000 living in the various statistical sub-divisions of a town ; the death-rates are also given for these areas from the five principal classes of disease ; the deaths occurring in public institutions having been distributed.

*Table E.* Gives the population of the annual rate of mortality occurring in a town at five groups of ages, compared with the English life table rate at those ages for males and females.

*Table F.* Shows the principal causes of death in combination with ages at the five selected groups.

*Table G.* Gives the deaths from several specified causes without distinction of age occurring in the various wards of the borough, and also the deaths occurring in the various public institutions.

*Table H.* Gives the number of deaths and proportion of deaths certified by medical practitioners, by the coroner, and the number and proportion of uncertified deaths.

*Table I.* Gives the annual rate of mortality during the twelve months from the five classes of disease at five groups of ages per 1,000 persons estimated to be living at those ages.

*Table J.*—Gives the prices paid by the Poor-law authority for the principal articles of food and fuel.

In the discussion which followed, the President, Dr. Longstaff, Dr. Tripe, Mr. Humphreys, Dr. Browning, and Mr. Shirley Murphy, took part.

## DOES THE GENERAL MEDICAL COUNCIL REPRESENT THE MEDICAL PROFESSION ?—II.

### THE INDIRECT REPRESENTATIVE.

WE last week discussed the methods of election of two sections of the General Medical Council, *i.e.*, the Crown nominees and the representatives of non-medical or self-elective governing bodies, and we endeavoured to show that over the election of the twelve members who are included within these two classes, and who constitute one-half of the Council, the medical profession exercises no control worthy of the name, and therefore cannot be considered to be represented by them.

The next class of representatives to whom we have to refer are those who are elected by the executive councils of the bodies corporate, those councils being themselves to a greater or less extent subject to election by the entire voting constituency.

These *indirect* representatives are but three in number, even if we include amongst them the representative of the Queen's University, although the medical graduates of the University possess only a nominal control over the election of the Senate which elects the representative.

*Licensing Bodies whose Representative is Elected indirectly under Vote of the Members.*

| Name. | By whom representative elected. | Number of Electors. | Number of Medical Electors. | By whom Electors Appointed. |
|---|---|---|---|---|
| 15. College of Surgeons of England | The Council .. | 24 | 24 | The whole of the Fellows 1,300 in number |
| 16. College of Surgeons of Ireland. | The Council .. | 21 | 21 | The Fellows, about 350 in number |
| 17. Queen's University in Ireland. | The Senate .. | 25 | 4 | 18 by the Crown, 6 by the Convocation |

The members herein referred to may claim to represent the medical or surgical graduates of their colleges, only in so far as those graduates can make their influence felt by the Council who exercise the electoral function. We hold that indirect representation of this sort cannot be held to convey the opinions of the constituency of a licensing body, for the exercise of such an elective power is but one out of the many administrative duties of a Council, upon the performance of which the constituency has to express its opinion; and in fact circumstances can hardly be conceived which would afford the constituency the opportunity of condemning the conduct of its Medical Council representative. The representation of the medical profession is therefore (in cases in which the representative is chosen by the executive body) altogether nominal and unreal.

For example, let us ask how the Fellows of the Irish College of Surgeons could act if the representative of that College saw fit to adopt a policy or take action of which they disapproved? In such case their only course would be to expel from the executive Council of the College those members who they conceived would be likely to support the re-election of the Medical Council representative, they having no knowledge as to who had actually done so. It must be remembered that the Fellows have no power to dismiss their representative by removing him from their College Council, for—by the Medical Act—he need not be a Member of that Council, or even a Fellow of the College, or, we believe, even a medical man. Thus they would be obliged to make the question of re-election a crucial test of the fitness of a College Councillor for his seat, and would be obliged to wait for the day of election to make their views felt. It is obvious that this amount of control over the representative means no control at all, and therefore no representation, and we appeal to experience of the twenty years' working of the Medical Council to prove that even on occasions when the medical or surgical graduates of a college have strongly disapproved of the acts of their *soi-disant* representatives (and we know that there have been such instances), they have never attempted to express that disapproval, or to exercise their nominal control.

But we will go further than a mere enunciation of the expediency and the fairness of giving to the elective constituencies of colleges the right of electing their Medical Council representative, for we entertain no doubt that in certain instances at least the electing of a representative on the General Medical Council by the executive Council of a College is a perfectly illegal assumption, based perhaps upon a vagueness in the Medical Act, and a consequent misconception of the law, but none the less illegal.

In the absence of means of expression of professional opinion, it seems, without doubt, to have been intended that the members of the body corporate of each licensing body should be the electors of the General Medical Council; and we therefore maintain that in the cases at least of certain of the delegates to that body their election has been habitually illegal, and that their tenure of office might be voided by any one who possessed a *locus standi* as a qualified corporate voter, and who thought fit to test the validity of such election before the courts of law.

It would seem from a reference to the successive legislative measures which occupied the attention of Parliament before the Medical Act of 1858 became law, that it was always the intention that the elected representatives should be chosen by the full voting constituencies of the Colleges which they represented, and in the existing Medical Act this intention is expressed and inferred. The clause (4) which provides for the matter says that "The General Medical Council shall consist of one person chosen *by each of the* following *bodies*." And again (clause 6), "The members chosen by the Medical Corporations and Universities" shall, &c.

What "body" it is which constitutes "the College" or University is, of course, a legal question, to be decided upon the statutes and charters of each individual body, and it may be that some of those statutes constitute the governing council the body corporate of the institution, in which case the election of a Medical Council representative by such governing conclave would be perfectly *intra vires;* but in the case of some of the licensing bodies "the College" consists, undoubtedly, of the entire voting constituency of its members, and we fully believe that in them, and them alone, lies the elective power. In the King's and Queen's College of Physicians that power is actually exercised by each member of the body corporate, and though those members are few in number, their legal right to elect is, nevertheless, fully recognised. In the Royal College of Surgeons in Ireland, on the other hand, the Fellows number over 300, and they meet in considerable numbers once or twice yearly for the purpose of exercising their elective rights, which are fully recognised throughout the College charters. Yet the representative of the College in the General Medical Council is chosen, not by them, but by the College Council, and over the acts of that representative the Fellows of the College have only the very limited and indirect influence which we have defined above.

We maintain, therefore, that the first most obvious and most necessary change in the constitution of the General Medical Council should be to restore to the voting members of medical bodies corporate the rights of election which the Medical Act gave them, and which have been quietly appropriated by the limited number of individuals who administer the affairs of those bodies. We challenge the representative function of members of th General Medical Council who hold their seats upon such tenancy, and we insist that they cannot claim to be the exponents of the wishes and opinions even of their own Colleges.

## THE REPORT ON THE EDUCATION OF THE GENERAL PRACTITIONER.—II.

After advocating an attempt to raise the status of the men commencing to study medicine, and a further attempt at weeding out the idle and incapable men at the end of the first year, the committee went onwards. The first question put is as follows:—"Is it desirable that, after passing the primary professional examination, every student should be compelled to devote two full years to clinical medicine, surgery, and obstetrics, at a hospital, prior to being allowed to present himself for his final, or qualifying examination?" Ninety-two (92) per cent. of the teachers of medicine and surgery, and ninety-seven (97) per cent. of the general practitioners, answered this question in the affirmative. It seems that after such a strong expression of opinion the committee did not consider it necessary to discuss this subject. We conceive that the word "primary" here has reference to the present "primary" examination, and not to the new examination which it is proposed should be made at the end of the first year. Undoubtedly it is very desirable that such a period be so spent; but a few words as to how it would be best spent may be permissible. At present there are eleven hospitals in London, where the teaching of students is carried on; some of them large, some of them small. Now, it is clear that at the large schools there must be large clinical classes where good men can get on well, can come into personal contact with the teacher, and can learn a very great deal. But the idle man can shirk almost to any length, and practically hide himself in those large classes; and though he be present in the flesh with admirable punctuality, may be as absent in the spirit as he pleases, almost. It cannot be expected that the clinical teachers of large schools can personally look after all the idle men in their classes. The late Prof. J. Hughes Bennett, of Edinburgh, was given to stirring up the idle men in a very energetic manner. He would pick one out and make him examine a patient, putting him "through the small sieve" mercilessly; and by thus making an example of him and his order, kept every fellow pretty well up to the mark. The late Dr. Murchison did the same thing very thoroughly, only he asked each student if he might put his name down on a card kept for the purpose of telling who were willing to be "dressed down," and he never made a victim of the men who shirked. But Bennett never could put a student "through his facings" more effectually than Murchison did these voluntary offerings. But it is not every man who possesses the energy to conduct such clinical examinations, or the force of character to carry the plan out thoroughly. It is, too, a form of clinical teaching that will never be generally adopted. At the smaller schools every man is known to his teachers, and the idler cannot escape altogether: consequently the smaller schools possess certain advantages over the larger ones for the idler and the man of mediocre abilities. But this fact can bear little practical fruit, for parents would scarcely estimate their boys as idle or dull, in selecting the medical school to which to send them. Their choice is made on very different grounds to these. At the small schools every man is known and looked after to a greater or less extent. At the large schools this is not, and cannot be, the case; and the dull man and the idler are, practically, comparatively neglected. In order, then, to meet this difficulty the Committee put a sixth question, which runs thus:—"Is it desirable that the clinical teachers of medicine, surgery, and obstetrics, should be required to testify as to their personal knowledge of the diligence and acquirements of each student (in place of the formal certificate of attendance now supplied), and that such certificate should be placed before the examiners for their information and guidance?" Forty-seven (47) per cent. of the teachers of medicine and surgery, and seventy-eight (78) per cent. of the general practitioners were in favour of the principle here advanced. It was held by a large number, more than half, of the teachers that this is undesirable, their arguments taking the following directions. Such action would tend to transfer part of the duties, the responsibilities, the authorities of examiners upon teachers. On the other hand, certificates from teachers would be of unequal value, might favour one man, or tell against another; and again, all teachers do not act with equal conscientiousness and precision in writing out forms, and what would seem but an indifferent testimony from one man would be high praise from another. If the clinical examinations be properly conducted such certificates are unnecessary. And it is to the thoroughness of these clinical examinations that apparently we must look for the future improvement in the practical part of medical study. Physical examination must be learnt at a hospital, if it is ever to be learnt at all. Men who leave their hospital without knowing how to examine the chest fairly well, will in all probability never achieve the power. They never, perhaps, become acutely conscious of their ignorance; and if they do they do not know how to start to remedy it. Students must be made, if necessary, to attend more to the wards and to the out-patients' rooms than has been the case in the past, and is too much the case yet. But even then, however industrious and painstaking, they cannot learn there that way of examining and interrogating the patient which is requisite for success with well-to-do private patients. The young men mentioned in the preceding division of this article, who would every day get up an old gentleman's night-shirt to examine the back of his lungs, with a female relative present, evidently in their hospital-acquired enthusiasm quite overlooked the inconvenience the patient would be put do, and the disagreeable impression such act would make upon the lady. Instead of looking forward to the doctor's visit with pleasure as the event of the day, they would regard it with repugnance, and probably take the earliest possible opportunity to call in some one else. A general practitioner must possess, of all medical men, something more than mere knowledge of his profession. For consultants who are not brought into so close associations with their patients knowledge is the cardinal requisite; but with the general practitioner, who is brought into close and intimate relations with patients, tact and keen observation as to the mental attitude of individuals, their moods and ways, is as absolutely necessary as professional knowledge. But how is the medical student to learn this? and where must he study practical psychology? He can not pursue this study in an hospital, and can only learn it in actual private practice. How often have we heard men of experience say, "we used to look forward to having a London M.D. among us, who would be 'up' with the latest information, and whom we could call in consultation in difficult cases. But when he came we found that patients would not have him a second time. They and their friends detected at once that he was not at home in a sick-room, and they measured him accordingly." Here the man's real knowledge had no chance given it. The patients and their friends knew little about his college honours and his real knowledge; they observed his want of familiarity with a sick room, and they would have none of him. Where under existing circumstances are students to become familiar with children and the peculiarities of their maladies and their management? A mother, intensely anxious about her child, scrutinises the young doctor when called in with microscopic minuteness and the most suspicious watchfulness. His utter want of acquaintance with babies is soon apparent, and she, again, will have no more of him. A man must learn somewhere and it is clear then, in his own interests, he should not have to acquire the knowledge in the locality where he proposes to reside ultimately. He must go as assistant to some general practitioner and learn all this, or as much as he can acquire from this teacher. It is as essential for the M.B. who proposes to enter general practice that he should be assistant to a good class general practitioner, during the interval which intervenes betwixt the M.B. examination and the M.D. examination, as that the same time be spent as resident in a good hospital by the man who aspires to be a consultant.

The Committee felt that something more and outside the present general medical education is desirable from the form in which they cast their seventh and last proposition. After endorsing the opinions given about the above six questions, they concluded that:—"Students, before going up for their final examination, should produce certificates of attendance at clinical instruction in the diseases of women and children, mental diseases, and also in ophthalmic medicine and surgery. Students should be acquainted with the elements of practical hygiene." Taken altogether this report merits approval, though it may not be easy to see how some of the projected reforms are to be carried out. For instance, how is a youth to learn dispensing along with the elements of botany, physics, biology, and inorganic chemistry, at the same time, unless he can be placed with a general practitioner located where certain educational advantages can be had. It would be next to impossible for the most enterprising youth to educate himself in the country: for very few country practitioners could help him much to any knowledge but that of practical dispensing. The only feasible scheme that suggests itself to our mind, after considering the matter for years, is this: That every medical student, good, bad, or indifferent, ought to spend his vacations in the country, where he could combine the study of the social side of his profession with opportunities for seeing patients himself; and at times with the responsibility of a practice on his hands. It is only the latter which will ever open a man's eyes effectively to the necessity for practical knowledge. Most men experience this after the die is cast, and no opportunity remains for well-directed study. By such plan the student would carry to the rural practitioner the most recent advances in the schools and teaching hospitals; and the student would bring back to college with him some rational comprehension of the requirements of general practice. This should be further supplemented by two years as qualified assistant with a man in good general practice, and then the young doctor could start for himself with a fair chance of avoiding mistakes, and of doing his professional knowledge justice.

# Notes on Current Topics.

## The Protection of Adulteration.

We have on many occasions spoken of the tolerant attitude of the English Pharmaceutical Society towards adulteration, and have inveighed against that Society undertaking to defend persons who are prosecuted for sophistication of drugs. We think it fair that no misapprehension should exist upon the subject, and we, therefore, quote a speech of the President in reference to a recent successful defence of a chemist charged with selling adulterated cream of tartar. "The cream of tartar in this case," he said, "was simply contaminated with the tartrate of lime "which was inherent in its preparation, because, according "to the Pharmacopœia, bitartrate of potash was to be made "from argol, and argol contained tartrate of lime; there"fore, he thought that any prosecution of a chemist for "selling cream of tartar, which contained no more tartrate "of lime than 6 per cent., was a vexatious prosecution, and "a proceeding against which the Council ought to fight. "At the same time, he must say that he felt the Society "stood on very delicate ground in this matter, because its "members should be the last persons to encourage any"thing like a sophistication of drugs. That could not be "too strongly put forward. Anything like real adultera"tion would be at once discountenanced by that Society, "and he did not wish it to be understood that it was its "business to defend everyone prosecuted for adulteration, "but rather to establish a general principle that there were "one or two articles, such as cream of tartar, sweet spirits of "nitre, and scammony, to which the special provision he "had quoted would apply." Mr. Hampson thought "no one at that board had any desire tocountenance adulteration in any possible form, but the Society, besides having important public functions to carry out, was a Society of members of the trade, and by its charter was distinctly empowered to protect those who carried on the business of chemists and druggists."

Probably the Council of the Society knows its own business best, but we think that it can never be free of the imputation of protecting adulteration as long as it allows itself to be represented as a Society "to protect those who carry on the business of a druggist," and as long as it accepts the duty of deciding how much or how little adulteration is deserving of its official approval. We should think that cream of tartar manufacturers could take care of themselves, and make profits large enough to enable them to pay for legal help when needed.

## Indecision of the Examiners at the Royal College of Surgeons, England.

At the last examination for the diploma of membership of the Royal College of Surgeons, there occurred a remarkable illustration of the indecision of the examiners respecting the manner in which candidates are expected to frame their replies to the questions set. As has been pointed out to us, quite truly, this is a subject of importance to candidates. We would therefore draw the attention of the College to the instance, and urge the advisability of an agreement among them, in future, with regard to the importance to be attached to the phraseology in which their questions are couched. The complaint made to us is as follows:—The presiding examiner in one room being appealed to, whether in answering Question 1 (describe the several structures which must be divided in an amputation of the thumb and its metacarpal bone), a full account of the muscles need be given announced that a *description* of the structures must necessarily include the enumeration of the origins and insertions of the muscles cut through. The same inquiry having been propounded to the president in a second room, answer was given that the various muscles need only be *named*. Now, it is evident that these two gentlemen, differing in opinion as to the mode in which the same question ought to be answered satisfactorily, would be likely to vary much in their estimate of the papers presented to them, and thus the success of a candidate might be in some degree imperilled through a simple misunderstanding. He who thought the question called for enumeration of names only, would regard as redundant the fuller descriptions which his *confrère* considered an essential part of the reply. The matter may seem a trivial one, but it is, nevertheless, important to students under examination, and we would suggest that, in their interest, it is but fair that they should have the fullest information about those details over which they will be expected to spend their time; none too much as it is.

## Medicine at Cambridge.

The interest felt in Cambridge in medical subjects considerably exceeds that taken in them at the sister University, the explanation probably being in the fact that Oxford with all its rich endowments, and spite of its nominal possession of paid chairs in the branches of medicine, is nevertheless a medical school only in name. With a flourishing school of medicine it is surprising that until the present time Cambridge has had no special society at whose meetings professional topics should be discussed. It is true the Philosophical Society affords some opening for the introduction of subjects bearing on medicine and surgery, but this has been quite insufficient to supply a need which is now met by the foundation of the "Cambridge Medical Society." Prof. Paget is the first president of the Association, Prof. Humphry vice-president, and Dr. Creighton secretary and treasurer. The meetings will be held monthly, except in September, on the first Friday in each month, the time to be alternately 3 p.m. and 8 p.m. The chief medical men of the town and neighbourhood have already become members.

## The New Registrar-General.

The Government have returned a reply to the protest of the British Medical Association against the rejection of Dr. Farr's claims, which is at once unsatisfactory and unbecoming the dignity of the profession. To be told that the Government had "good reasons" for the proceeding it has followed is to be told nothing; and in this matter the considerations involved are especially such as only those who estimate the importance of sanitary statistics on the progress of hygienic science, can accurately weigh. The conduct of authority in this appointment has been marked by an apparent neglect of the public welfare, which no amount of arrogant refusal to enter into details of explanation will suffice to cover; and now that the grave scandal has become the by-word of the lay journals, there is more than ever reason to demand that a searching inquiry into the facts which decided the appointment, shall be made. An unworthy effort to shift the blame of the affair on to Dr. Farr's own shoulders has lamentably broken down; and we do not see that that gentleman will be at all derogating from his eminent position by supporting the claims he has to the only suitable recognition of his incalculable services to the world. Beyond this, however, the supreme question of public health is involved; and for the Government to whom its safety is committed, the first consideration should be its preservation. That very much of the improvement in sanitation is the direct consequence of Dr. Farr's labours cannot be disputed, and it is a grievous loss that is being suffered by the substitution for those labours of the untried, unknown performances of the gentleman who has been placed in office over Dr. Farr.

## Lay Criticism of Professional Men.

A series of articles on "Our Doctors" is just now appearing in Mr. Edmund Yates' clever monthly, *Time*. The first of these contains a sketch of two practitioners, whose names are given as Sir Wm. Seamew and Dr. Peter Parsons. It is needless to say that the first is intended for Sir William Gull, further proof, if necessary, being afforded by an admirably like vignette of the physician appended to the foot of the article. The author has very happily contrived to give his reader an impression of his subject that will appeal to everyone who has any acquaintance with Sir William Gull; and it is pleasant to note the appreciation of the skill and wisdom born of experience, that is evident on the part of the essayist. Though somewhat sportive in tone, and written in a spirit of pseudo-satire, the article is a thoughtful *résumé* of the principles by which the treatment of the physician is formulated. There is something gratifying in the recognition of worth, and the assurance that the outside public are ready to accord the word of admiration and praise to those who are the healers of their pains; and particularly is this so now, in the presence of those utterances of a few, which are made in the attempt to depreciate the labours of those who have raised themselves by their powers to the summit of professional success. We shall return again to these cheerful little papers, for they are well worthy of being dwelt on.

### The Audiphone.

We recently drew attention to this instrument, which was exhibited at the *conversazione* of the Harveian Society; and we expressed some doubt as to its efficiency in the direction claimed for it. In confirmation of our opinion, the *Chicago Medical Journal and Examiner* says, "Messrs. Sharp and Sons have been carefully testing the audiphone for several weeks, but thus far they have not found any patients benefited by it. Out of 150 successive cases of deafness, in which they have given it a trial, they report that not one single one has noticed any benefit in its use."

### The Lane Testimonial.

The veteran consulting surgeon to St. Mary's Hospital, Mr. James Lane, was presented with a valuable silver centre-piece for the table on January 21st. On the occasion a dinner took place at the Pall Mall Restaurant, the presentation being made afterwards by Dr. Broadbent, who feelingly referred to the services rendered to the St. Mary's School by the guest of the night.

### Royal College of Physicians of London.

At the ordinary meeting of this College on Thursday last, the President brought forward a proposal that had been made to hold a Medical Congress in London in 1881, and it was resolved that it was desirable such a Congress should be held, the President being authorised to take, conjointly with the President of the Royal College of Surgeons, the necessary preliminary steps.

At the same meeting Drs. Dickinson, Brunton, and Ferrier were appointed to adjudicate the Benett-Stanford prize; and Drs. S. Wilks, W. H. Stone, Wilson Fox, and G. Buchanan were elected Councillors of the College. The report of the Examiners for 1879 was next presented, which showed a material increase over previous years in the number of candidates for the College diplomas. The rejections in 1879, compared with those in 1878, point to an improved preparation on the part of those who presented themselves; for although the standard of examination had been maintained, the rejections were much fewer than in the previous year.

### Registration of Military Rank in the Medical Register.

The following resolution has been adopted by the Irish Branch Medical Council:—"That this Branch Council regret to learn that a systematic attempt is being made to introduce into the 'Residence' column of the copy of the General Medical Register, now being printed, the designation of the 'rank' of, or offices held by, naval and military officers, such not being warranted by the Medical Act (1858), or by any of its Amendments."

We had been aware that the proposition herein referred to had been made, but did not think it necessary to notice the fact, feeling assured that the Executive Committee of the Medical Council would see the illegality and inexpediency of adding to or taking from the statement of name, residence, and professional licences which appear in the Register. We know of no authority in any of the Medical Acts for such addition, and if such authority existed, we see no reason whatever why the honour of registering their official rank should be restricted to military and naval officers. If army surgeons are to be specially enrolled, why not the Queen's physicians and surgeons?—why not University professors?—and then what next!—why not *soi-disant* lecturers in every proprietary hospital?

If the law which restricts registration to medical qualifications be ever relaxed, its first extension should certainly be to include degrees in Arts. In these days professional rank greatly depends on Art qualifications. There are M.D.'s and M.D.'s—one class who have won their rank by superadding to their medical degree a full graduation in Arts, gained after four years' continuous study and many examinations in a University; the other class, who have presented themselves at certain Universities one day and come away the next with the degree in their pockets, or who are medical licentiates whose connection with a University was purely the nominal tie of a formal matriculation, the usual preliminary examination, and perhaps a few weeks' attendence on lectures.

If distinctions are to be made in the Medical Register, we are strongly of opinion that the line of demarcation should be drawn between these classes by granting to the *bona fide* M.D.s the right to register their University Arts degree, and we are not without hope that the Medical Reform Act, which we understand will be presented early in the Parliamentary session, may be made to contain a clause for this purpose. Such an amendment was proposed in the House of Lords last year by the Earl of Courtoun, upon the suggestion of the University of Dublin; but it was then withdrawn, in order that the Bill might go to the Commons unopposed, and with the intention of re-opening the question in the Lower House when the Bill came down for committee. As it did not reach that stage, of course the proposal is still in suspense.

### The Prevention of Street Accidents.

The increase in the number of street accidents has caused an outcry which we trust will not easily be stayed. The society started under the auspices of many well-known and much respected noblemen and gentlemen, held its first annual meeting at the Mansion House last week. We are not a little gratified to find that "the Society for the Prevention of Street Accidents," dates its origin from an article in our columns commenting on the lamentable death of a greatly respected member of the profession, John Oakeshott, who, it will be remembered, was killed at the Northumberland Avenue by a reckless driver of a ginger-beer van. Lord Templeton, commenting upon the reckless driving going on in our streets, observed "that the drivers of vehicles had an idea that the roadways of London belonged to themselves, and therefore any man, woman, child, or dog, was looked upon as an intruder on their domain, and deserving of death." Last year no fewer than 237 persons were killed in the streets, and 3,399 were run over and taken to the hospitals. This is, indeed, a fearful butcher's bill, one demanding the most serious consideration of the Government and of those in authority. The Street Accident Society, acting in the interests of the public, demand better police supervision, better lighting, more refuges, justice to those who are maimed, and compensation to the friends of the killed. If the proprietors of cabs, carts, waggons, &c., were fairly brought under Campbell's Act, they would cease to employ reckless drivers. Of the other proposals for lessening the evils, the want of more street lights was insisted on. No other city in the world is so badly lighted as London. The street-lamps are placed too high and too far apart. This fault was felt as a most serious danger during the foggy days and nights of last week, when pedestrians and vehicles encountered each other in all directions. The names of streets should certainly be written on the street-lamps. This would greatly facilitate the benighted and befogged wayfarer. In most of the large Continental cities every vehicle after dark is compelled to carry a lamp. Why cannot this be done in London? In another way a good deal of relief would be obtained if the traffic were placed entirely under the control of the police. In Paris, during fixed times of the day, all heavy vehicles are excluded from the more frequented streets. In London little or nothing is attempted, except about the more fashionable spots and the more crowded thoroughfares. The slow, lumbering waggon and dust-cart, driven by besotted drivers, the reckless railway van and omnibus, all side by side with hansom cabs, butcher's and light carts, which dart about in all directions, defying the most careful person to calculate his crossing from one side of the street to the other. It is lamentable to find that thousands of families are made to suffer mutilation and death from reckless driving. But so it is and will be, until the police are fully empowered to deal with it; until furious driving is made punishable, not merely in theory, but in practice; until some effort is made to regulate the traffic, to put a stop to racing omnibuses and ginger-beer vans, and to loitering cabs; and to thoroughly recognise the positive right of ratepayers to cross the streets, for the lighting and paving and protection of which they are heavily taxed.

## The Census of 1881.

We have been favoured with a copy of the Report of the Committee of the National Social Science Association on the forthcoming Census, a bill upon which will, we understand, be introduced during the present Parliamentary Session, by Mr. Sclater-Booth, president of the Local Government Board. Last week a deputation from the Association waited upon this gentleman at his official residence in order to bring before him the views of the Committee, which may be thus summarised:—1st. That it is essential that all the particulars given in the Census for each part of the United Kingdom, 1871, be repeated in the Census, 1881, with such amendments in detail as may be found desirable. 2. That it is desirable that, as far as practicable, the Census for each part of the United Kingdom contain similar information, and be the same in form. 3. That it is desirable that in the Census of England and Scotland, as in the Census of Ireland, in 1871, the religious profession of each inhabitant be ascertained, and that this inquiry form part of the Householders' Schedule. 4. That it is desirable that in the Household Schedule there be a column for sickness or injury in the following form—"Sickness or Injury." Sick to include all who require medical advice, or who are disabled from following their usual employment. Write the name of disease from which the patient is suffering. 5. That it is desirable that a return of the number of rooms in each house be given in the Census of England and Wales and in that of Ireland, as has already been done in the Census of Scotland. 6. That it is desirable that houses be distinguished between those intended for habitation and those not intended for this purpose. 7. That it is desirable that there be a return of houses intended for habitation which are unlet. 8. That the returns under the head of occupation be amended to show the nature of the employment with greater precision. 9. That for every city and town the concentrated population, and the area which it occupies, should be returned, whether its boundaries be coincident or not with any legally defined boundary or boundaries. 10. That in the case of towns and other areas of concentrated population, summaries of the returns be made up and recorded for each enumerator's district, and be open for inspection at the offices of the Superintendent Registrar. 11. That the Census should be quinquennial, instead of decennial as now, each Census to be complete and to contain full particulars.

## Registrations and Erasures of Qualifications.

The controversy respecting the registering functions of Branch Medical Councils, to which we recently referred, is still in full vigour between the Irish Branch Council and the Executive Committee. Though the point raised is not a very important one to the profession, the principle involved is of interest as affecting the continued existence of the Branch Registration Offices in Dublin and Edinburgh. Our readers remember that by the Duke of Richmond's Bill, it was originally proposed that all the registration work of the profession should be centralised in London, and, although that proposal was struck out, the policy which gave rise to it still exists in the Executive Committee, and it is contested energetically by the Irish Branch.

The chief question now at issue is whether a change of residence or an additional qualification obtained by a person already registered, should be entered in the local office, where the name was originally inscribed, or should be registered in the London office. For instance, A.B. was registered, upon obtaining his qualification in the Dublin office, he being then resident in Ireland. He migrated to England, and notified his change of residence to the London office, where it was duly recorded and published in the Official Register. But no notification of the change was made to the Irish office, which accordingly retained A.B.'s original address. After a time, the Irish office, as required by the Act, sent letters to him at that address, and receiving no reply, removed his name altogether from the Register, and sent note of the fact to the London office, when it was discovered that A.B. was there duly registered for another residence. The Irish Council claims that the London office should either have referred A.B. to it for alteration of address, or at least, should have notified the alteration in order that the books of the Branch might be corrected, and the opinions of several learned counsel have been taken on both sides, all of which opinions, as might be expected, have differed in material respects. The last contribution to the law of the question is from the English Solicitor-General and Mr. Vaughan Hawkins, Q.C., who, while admitting that the alteration must be made in a "local" registry, consider that any local registry will do, and that a Scotchman may register the alteration in the Dublin office, if he pleases, and *vice versa.* This opinion obviously concedes the point which the Irish office contends for, because it would be plainly impossible to carry on the business of registration under such law, unless the three offices made a practice of notifying the changes to each other. But whatever the law may be, there can be no question that registration could not be satisfactorily carried on, and the profession would be seriously inconvenienced, if the refusal of the central office to inform the Branch offices of its entries were persisted in. If the Executive Committee wishes for centralisation it must centralise in a legitimate way (if it can) by a change in the law, but it must not prejudice the accuracy of the Medical Register by attempting to force that centralisation in an underhand way.

## The Archbishop's Medical Degree.

His Grace the Archbishop of Canterbury has conferred a medical degree on Mr. James Rogers, of Swansea, who was Mayor during the recent Church Congress. The medical law of England, by the Act of 1858, only recognises such doctorates as were conferred before the passing of that Act. The Government Bill now before the Select Committee of the House makes no provision for the degree, which three doctors of medicine, two being Fellows of the College of Physicians, recommended. The *Students' Journal* informs us that Dr. Rogers has practised in Swansea and the neighbourhood for nearly 40 years, and is much respected by his neighbours and professional brethren. The expenses of the degree, about 80 guineas, have been more than met by subscriptions, men of all classes in Swansea uniting to pay them.

We should have thought that Dr. Rogers would have got quite as good a proof of professional education from some of the American Colleges for less money, and without having to leave Swansea; and we certainly would also have thought that the head of the English Church would rise superior to the earning of 80 guineas by the sale of an illegal degree. The transaction is certainly a strange one, considering that at the moment when his Grace is granting sham degrees Parliament is about to reopen the general question of medical reform.

## Injection of Corrosive Sublimate in Syphilis.

M. Sterne, of Breslau, recommends the following solution: ℞ Bichloride of mercury, ·25 gramme; chloride of sodium (pure), 2·05 grammes; distilled water, 50 grammes. One cubic centimetre (about 15 grains) to be injected daily. This method causes the syphilitic symptoms to disappear in a relatively short time; it necessitates the employment of only small quantities of mercury; it does not produce local inflammation; the general condition is in no way troubled by it; the stomatitis is insignificant; it is easier and better than inunction.

## Treatment of Pemphigus.

*La France Medicale* says M. Hardy prescribes for pemphigus the following treatment: ℞ Arseniate of iron, 1 gramme; conserve of roses, q.s. to make 100 pills. One to be taken morning and evening at the beginning of breakfast and dinner. After a week, one morning, noon, and evening. Externally, the skin of the patient to be sprinkled with starch powder. If there is suppuration, to be dressed with the following liniment—lime water, 40 grammes; olive oil, 60 grammes. This to be combined with tonic regimen.

## Functional Spasm of the Sterno-Mastoid.

At a recent meeting of the Société Medicale des Hopitaux, M. Desnos exhibited a patient affected with functional spasm of the sterno-mastoid, which she had had for two years. About a year ago, she became pregnant, and during the early months of pregnancy the phenomenon somewhat subsided, returning with increased force after delivery. When she lies down there is noticeable only slight deviation of the chin; but when she wishes to make an effort there is evident spasm of the sterno-mastoid, and also the trapezius, the two muscles supplied by the spinal accessory nerve. Electricity and iodide of potassium have had no effect.

## The Treatment of Lupus by Linear Scarification.

In a paper read before a recent meeting of the Academie de Médecine, M. Vidal after carefully reviewing the subject, concludes that the external treatment of lupus by scarifications is the least painful, the most certain, the best protection against recurrence, and gives the best results with respect to the formation of a regular cicatrix. Though applicable to all varieties of lupus, remarkably efficacious in curing the tubercular forms, ulcerative and non-ulcerative—and even lupus exedens—it is less efficient in lupus erythematosus, and still less in acneform lupus.

## The Irish Certificate System.

We observe from the Minutes of the Irish Branch Medical Council that the replies received from certain of the medical schools and clinical hospitals having been submitted, it was resolved,—

> That the consideration of this subject be postponed to a future meeting, when the returns from all the medical schools and clinical hospitals shall have been received.

The replies herein referred to are the answers to official inquiry as to what steps these schools and hospitals take to record the attendance of students and to ensure the truthfulness of their certificates of "diligent" attendance. It is to be regretted that the Branch Council after the lapse of several months has not been able to collect these replies, and finds it convenient to defer the matter *sine die.* The executive Committee of the General Medical Council is holding just now possibly its last meeting before the assembly of the General Council, and it certainly seems that if the Branch Council had not been unwilling to press inconvenient questions it might have extracted these replies before this date.

## Habitual Drunkards.

On Monday evening Dr. Alford opened a discussion on the legislative restrictions to be imposed on habitual drunkards, at the Social Science Association's Rooms, Lord Shaftesbury presiding. The paper was an exhaustive one, dealing in full with the subject, and containing a very complete *resumé* of the legislative and other action which has already taken place in the matter. As we were at press while the discussion was in progress, we are unable to print a report of it in this number. We shall revert to it, however, in our next issue.

## The Diet in Convalescence from Typhoid Fever.

The caution cannot be too often given to patients and their friends, that the appetite which appears in the convalescence from typhoid must be most discreetly indulged. In the Medico-Chirurgical Society of Montreal, lately, Dr. Reddy mentioned a case which had been under his care in the hospital two years ago, where death took place from a relapse following a large meal of mutton chops. This patient had been well for three weeks. The post-mortem showed a perforation not larger than a pin's head at the bottom of an ulcer.

A marble statue to Bourgelat, founder of the Veterinary School of Paris, was unveiled in that city, October 30th.

The examinations of candidates for the Medical Departments of the Army and Navy will be held on the 9th of February at Burlington House.

The discovery that about forty bodies have been stolen, for dissecting purposes, at Richmond, in America, since cold weather set in, has caused much excitement in that city. The exhumed corpses are supposed to be those of coloured persons chiefly.

An example how memory is not necessarily a high faculty of mind, is illustrated in one of the children in the Pennsylvania Training School for Feeble-minded Children, in Delaware county. So retentive is his memory that, after listening to a sermon or other discourse, he is able to repeat it *verbatim*, even to the intonations of the speaker.

In the principal large towns of the United Kingdom the annual rates of mortality per 1,000 last week were—Oldham 19, Sunderland 19, Brighton 21, Edinburgh 21, Sheffield 22, Wolverhampton 22, Newcastle-upon-Tyne 23, Leicester 23, Norwich 23, Bradford 23, Portsmouth 23, Leeds 24, Bristol 24, Salford 24, Birmingham 25, Glasgow 26, London 27, Plymouth 27, Liverpool 28, Hull 29, Nottingham 30, Manchester 31, and the highest rate Dublin 40.

William H. Appleton, publisher of the New York *Medical Journal*, has been sued for 25,000 dols. damages, for libel, by a dentist named Thomas B. Gunning. It appears that after the attempted assassination of Secretary Seward, in 1865, Mr. Gunning performed an operation on his jaw. An article appeared in the New York *Medical Journal*, a few months ago, which contained reference to Mr. Seward's injury, and Mr. Gunning is of the opinion that it reflected on his competency as a dentist.

Last week the death-rate in the large towns from the seven principal zymotic diseases per 1,000, ranged from 0·7 and 0·9 in Wolverhampton and Oldham, to 8·4 and 10·8 in Plymouth and Hull. Measles showed the largest proportional fatality in Hull, Plymouth, Nottingham, and Leicester; scarlet fever in Dublin, Leicester, Bristol, Norwich, Bradford, and Sunderland; and whooping-cough in Salford, Newcastle-upon-Tyne, Dublin, and London. Small-pox caused 3 more deaths in London, 5 in Dublin, but not one in any of the nineteen large provincial towns.

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns, were—in Bombay 35; Paris 34; Geneva 21; Brussels 29; Amsterdam 39, Rotterdam 30, The Hague 28; Copenhagen 25; Stockholm 24; Christiania 18; St. Petersburgh 45; Berlin 26, Hamburg 31, Dresden 26, Breslau 29, Munich 34; Vienna 31; Buda-Pesth 34; Rome 42, Turin 39; Venice 45; Alexandria 36; New York 24, per 1,000 of the population. Small-pox caused 68 deaths in Paris; and 49 deaths were referred to fever in St. Petersburgh.

◆

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Prosecution under the Vaccination Act at Glasgow.—On the 30th ult., before Sheriff Spens, Mr. James Greig, of Granby Terrace, Hillhead, was charged at the instance of the Inspector of Poor for Govan, with having refused or failed to vaccinate two of his children. Mr. Greig pleaded guilty to the charge, alleging that he did not approve of vaccination for his healthy children, but argued that in respect of one of his children he was not again liable, as he had suffered a penalty for its non-vaccination about a year ago. The Sheriff repelled the objection, and imposed a penalty of 10s. for each offence, with 10s. of expenses incurred in his prosecution.

Prosecuting a "Doctor" in Shetland.—At the Sheriff Court, on the 20th ult., before Alexander Mitchell, Esq., Hon. Sheriff-Substitute, Hector Mackenzie, Chemist, residing in Lerwick, was charged with a contravention of the Medical Act, 21 and 22 Vic., cap. 90, sec. 40, in so far as he inserted, or caused to be inserted in the *Shetland Times* newspaper on the 13th, 20th, and 27th of December last, and on the 3rd ult., an advertisement in which he styled himself Dr. Mackenzie, U.S.A., whereby he wilfully and falsely pretended to be, or took or used the title of, a doctor of medicine, implying that he is registered under the said Medical Act, or that he is recognised by law as a physician, or surgeon, or practitioner in medicine, whereby the said Hector Mackenzie is liable in a penalty not exceeding £20. Mr. Macgregor, solicitor, appeared for Mackenzie, and objected to the relevancy of the libel. Mr. Galloway replied and the Sheriff repelled the objections. The accused pleaded not guilty, and proof was led as to the insertion of the advertisement having been ordered by the accused. John Scott Smith produced the latest edition of the *Medical Register*, and deposed that the name of the accused was not in it. George Mackay, Superintendent of Burgh Police, and Peter Urquhart, of County Police, proved that the accused practised as a doctor. Mr. Galloway addressed the Bench, and held that he had proved his case. Mr. Macgregor, for the accused, maintained that there was no proof that any person had been deceived by these advertisements. The Sheriff said that there was no doubt the Act was passed to prevent the public being imposed upon by unqualified practitioners. He looked upon the advertisements as intended to make people believe that the advertiser was a regularly qualified practitioner. What was Mr. Mackenzie's object in advertising himself as a doctor if he did not wish the people to believe he was one? He found the charge proven as libelled, and sentenced the accused to pay a fine of £10 and the Court expenses. The Sheriff's finding is to be admired. Such "doctors" infest almost all our large cities. Glasgow is rich in them, and the Procurator-Fiscal might be worse employed than in giving these gentry a little legal attention.

Edinburgh Dental Hospital.—The annual meeting of the directors and contributors of this institution was held on the 29th ult. in the hospital, 30 Chambers Street, Edinburgh, the Rev. Dr. Sandford presiding. The Honroary Secretary, Mr. James Robertson, stated in his report—the first since the inauguration of the institution—that the teaching staff had been fully organised, and the full curriculum recommended by the Medical Council, in conformity with the Dental Act of 1878, could now be obtained in Edinburgh. Special classes were commenced on the 4th November last in terms of the prospectus of the school, and had so far been well attended. A lease of the premises at 30 Chambers Street had been obtained for fifteen years from Whit Sunday, 1879, at the annual rent of £100, subject to certain reduction in favour of the directors, and with a break in their favour at the end of five and ten years. The report of the Medical Secretary, Dr. Wm. Chisholm, alluded to the great success that had attended the institution since the amalgamation with the Edinburgh Dental Dispensary. There was now a large increase in the number of applicants for assistance and professional advice, and up to the present time no fewer than 4,500 patients had received advice and treatment. The use of anæsthetics in difficult and protracted operations had been largely adopted. These operations, with the necessary material, had led to a considerable extra expense, but the staff looked confidently to the public to supply those means of assistance to the deserving poor. The Treasurer, Mr. Hepburn, said he produced the report with mingled feelings of satisfaction and disappointment. His satisfaction arose from the fact that although they had had a considerable outlay in furnishing and instituting the hospital, there still was a fund left in hand with which to begin the current year; but he was disappointed the public had not done more to support an institution which was the means of alleviating so much suffering. The receipts amounted to £369, and upwards of £200 of that sum had been contributed by members of the profession, while their Hon. President, Lord Rosebery, had given £60, so that the public had yet done very little. The expenditure amounted to £292, and there was a balance of about £70 in hand. The reports were adopted, and the proceedings terminated with the customary votes of thanks.

Glasgow Eye Infirmary.—The fifty-sixth Annual General Meeting of the contributors to the funds of the Glasgow Eye Infirmary was held on the 27th ult., in the directors' room of the Merchant House, Glasgow, Mr. James King, of Lovernholme, in the chair. The annual report was read by the secretary, Mr. George Black, and represented that the condition of the institution was satisfactory. The chairman remarked on the diminished subscriptions from the employés in public works, and hoped that they would soon resume their old position of being the mainstay of the institution. Mr. King was appointed President of the institution. The clerk was instructed to convey to Mr. Dalglish the thanks of the meeting for his conduct as president of the institution for so many years.

Edinburgh University Court.—The University Court met on the 26th ult., Principal Sir Alexander Grant in the chair. *Inter alia*, Dr. Alfred R. Duffin, F.R.C.P., Lond., Professor of Pathology, King's College, London, was appointed additional examiner in practice of physic, and Dr. William McIntosh, Murthly, was reappointed additional examiner in natural history. These appointments are for the current year, and may be held for five years by annual reappointment. The additional examiners in anatomy, physiology, surgery, pathology, materia medica, midwifery, clinical surgery, clinical medicine, and medical jurisprupence were reappointed for the current year.

Glasgow Royal Infirmary.—The Annual General Meeting of the contributors of the Glasgow Royal Infirmary was held on the 26th ult., in the Accountants' Hall, West Nile Street; Lord Provost Collins presided. The secretary submitted the directors' annual report, which included the medical superintendent's report and the financial statement. The medical superintendent's report stated that during the past year 5,320 patients were admitted into the hospital, being 21 less than the number admitted during the previous year. The daily average in the institution was 486, against 487 in 1878. The total number treated to a conclusion in the medical wards was 2,582, of whom 2,265 were dismissed cured, relieved, or from other causes, and 317 died. In the surgical wards the total number treated to a conclusion was 2,763, and of those 2,617 were dismissed cured, relieved, or from other causes, and 146 died. On the 31st December last there remained in th medical wards 182, and in the surgical wards 294. During the past year 59 patients died within twenty-four hours after admission; or extending the period to forty-eight hours, the number was 97. Deducting the latter number from the total deaths the mortality was reduced from 8·6 to 6·9 per cent. The number of children under 15 years of age treated to a conclusion in the wards was 151 medical and 603 surgical, in all 754, of whom 52 died. At the dispensary the number brought for advice under the same age was 6,258, of whom 3,086 were medical and 3,172 surgical. The number of out-patients treated at the dispensary was 21,251, of whom 12,185 were medical and 9,066 surgical. The total number who received treatment during 1879 in or at the different departments was 32,547, against 29,836 in 1878. Five hundred and eighty-six patients had been sent to the Convalescent Home at Lenzie. The financial statement showed that the ordinary revenue was £17,401 9s. 7d. and the expenditure £23,721 12s. 10d., the excess of expenditure being £6,320 3s. 3d., which was carried to the debit of extraordinary revenue. The extraordinary income amounted to £9,751 19s. 1d., and the extraordinary expenditure to £4,410 11s. 7d. The expenditure was thus £978 15s. 9d. in excess of the total income. The managers expressed their satisfaction that they had been able to treat so large a number of persons with so small a mortality. The Lord Provost in moving the adoption of the report, alluded to the decrease in the rate of mortality among the patients, the resolution of the directors that the medical officers should retire after a certain number of years' service, and expressed cordial approval thereof, and the decrease in contributions to the funds of the infirmary, &c. Mr. James White seconded the motion, which was unanimously agreed to.

## Obituary.

### SIR DOMINIC J. CORRIGAN, BART., M.D.

In the first hour of the first day of the present month this most distinguished physician peacefully passed away. On the 30th of December he was seized with hemiplegia of the left side, but so vigorous was his constitution that notwithstanding his advanced age partial recovery was hoped for. He was educated in Maynooth College, which then admitted lay pupils, and wherein he gained an extensive knowledge of the classics and of physics. Few were possessed of a more terse and vigorous style of English diction. With Dr. O'Kelly, medical attendant of the college abovenamed, he gained some of the rudiments of medical science and pharmacy, and after study in Dublin and Edinburgh graduated in the University of the latter city in 1825. Having shortly after settled in Dublin he successively worked at the Dispensary, Meath Street, Cork Street, Jervis Street Hospital, and the House of Industry. On resigning the physiciancy of the latter great institution he was appointed Consulting Physician and one of the Board of Governors. His earliest and most important contributions to medical literature were his essays on permanent patency of the aortic valves (1832), and on cirrhosis of the lung, which Sir P. Crampton, in an address before the College of Surgeons in 1838, said placed him "among the ablest pathologists of the day." He rapidly gained consulting practice, and in 1836 purchased the house in Merrion Square, wherein his decease has just occurred. Some fifteen years since his professional income exceeded that ever received by any other Dublin practitioner. Besides the essays mentioned his best known writings were a pamphlet on the connection between "Famine and Fever," which in 1846 warned the authorities of the impending tremendous epidemic, and "Lectures on Fevers," 1853. His communications to the Pathological Society were also numerous and valuable. Dr. Corrigan very early in his career lectured in the Dublin School of Medicine, and from 1843 until 1854 held the Chair of Physic in the Richmond Hospital School. There the writer of this hurried notice listened to his portrayal of disease, which for terseness and accuracy have probably never been excelled. He rarely lectured on each occasion for more than half an hour. From 1849, when he was appointed Physician to the Queen, distinctions crowded upon him, notably the Honorary Doctorate of the Dublin University, and the Presidency of the College of Physicians, which he held for the unexampled term of five years. The splendid hall of that body was erected owing mainly to his exertions, and it contains as memorials a stained glass window, a good portrait, and one of the great Foley's finest statues. The Academy of Medicine of Paris elected him corresponding member, but with this exception his conspicuous merit and eminence gained him no distinction in the sister isle or on the Continent. On the establishment of [the Queen's University Dr. Corrigan was placed on the senate, and in 1869 elected Vice-Chancellor. He was also appointed a Commissioner of National Education, and a member of the Board, which on two occasions inquired into the carrying out of the Lunacy Laws in Ireland. He possessed most brilliant powers as a debater, and was best known in England as a member of the General Medical Council, where his speeches were bold and original, tending, it must be confessed, towards obstructive tediousness for the past two or three years. On February 5, 1866, a baronetcy was conferred on him "in recognition of his very distinguished professional position, and also his great and gratuitous services connected with the health and education of Ireland." The title descends to his grandson, whose father, a most distinguished officer of the 3rd Dragoon Guards, died on January 6, 1866, just a month before the baronetcy was created. We may finally mention that Sir D. Corrigan represented his native city in Parliament from 1870 to 1874. In no way does the honesty and independence of his character appear more clearly than in his action at the general election. He was a warm advocate of Sunday closing and a consistent opponent of Home Rule and of denominational education, and it was perfectly well ascertained by political parties that his re-election was certain if he consented to yield, or, as too many did, appear to yield his opinions on these subjects. He firmly refused to do so, and thus sacrificed the great object of ambition for which he had resigned a splendid practice. It has been said that Parliamentary life broke down his health, but so far from the truth is this that it was a common habit for him to leave London by the Friday night mail and drive directly from the Dublin terminus to the Zoological Gardens to breakfast with the Council on the Saturday morning. Of that society he had ever been a most generous supporter, and for many years president.

◆

## DR. LOCKHART CLARKE, F.R.S.

We regret to report the death of Dr. Lockhart Clarke, who died from phthisis on the 25th January. Dr. Clarke commenced general practice in Pimlico, but soon taking a fancy for microscopical research, he devoted a large part of his time to science. His sections of the spinal cord in health and disease were among the first which attracted professional attention to its diseases, and in 1864 he obtained the medal of the Royal Society for researches on the nervous system. He subsequently engaged himself in consulting practice, taking diseases of the nervous system as a speciality, and attached himself as physician to the Hospital for Epilepsy and Paralysis, Regent's Park. Among his works and scientific papers were the "Spinal Cord," "Nervous System," "Intimate Structure of the Brain," "Structure of Olfactory Bulb and Mucous Membrane," "Nature of Volition," "Locomotor Ataxy" "Paraplegia," "Pathology of Tetanus and of Muscular Atrophy." "Diseases and Injuries of Nerves," "Treatment of Hysterical Paroxysms," "Epilepsy."

From the above list, it will be seen that few men have written more largely on the nervous system. The pathology of these subjects was thoroughly taken up, and the laborious work undertaken by him has led to much good scientific result in the hands of others.

## SIR DOMINIC CORRIGAN'S SUCCESSOR.

By the lamented death of Sir Dominic Corrigan, which we record in another part of our present issue, many offices of honour, though none of emolument, will pass to other hands. The baronetcy which was granted to him in 1866, in recognition of his very distinguished public and professional services, passes to his grandson, the only living child of Captain Corrigan of the 3rd Dragoon Guards. The young baronet attains his majority this year, and, as we understand, is now residing in Silesia. The vacated medical baronetcy, the blue ribbon of the medical profession in Ireland, will, it is hoped, be conferred without delay on one or other of the distinguished physicians of Dublin. Dr. Alfred Hudson, physician to the Queen, Regius Professor of Physic in Dublin University, and Crown representative on the General Medical Council; Dr. J. Banks, a Senator of the Queen's University, and ex-President of the College of Physicians; Dr. Head, the existing President of the same College; and Dr. Samuel Gordon, its President of last year, are spoken of as possible recipients either of the honour of baronetcy or of the office of Physician to Her Majesty which is also vacant.

Respecting the representation of the Queen's University on the General Medical Council, some doubts have arisen as to the capacity of the Senate to elect such an officer, and we are aware that the subject has been under their consideration. The University Education (Ireland) Act, secs. 11 to 15, provide for the continuance of the functions of the Queen's University until its final dissolution, which must take place within two years of the issue of the Charter which has just seen the light. The election of a Medical Council representative is not set forth in the continuing functions of the Queen's University, but, as it is provided that the University is not yet to be dissolved, we presume it is legally competent to send forward its representative to the Medical Council. Of that University Sir Dominic Corrigan was also Vice-Chancellor. He was also a governor of the House of Industry Hospitals, and, until recently, a member of the Dublin Hospitals Board.

# Medical News.

**Royal College of Physicians of London.**—The following gentlemen having passed the required examination, were admitted Members on January 29 :—

Fowler, James Kingston, M.B., Cambridge, 35 Clarges Street, W.
Huggard, William Richard, M.D., Queen's University, Hammersmith, W.

The following were admitted Licentiates of the College on January 29 :—

Alvares, Nicolas Santana, 24 Ampthill Square, N.W.
McKee, Gerald Macklin Eccles, 2 Overstone Road, W.

**Royal College of Surgeons of England.**—The following candidates having passed the required examinations, were duly admitted Members of the College at a meeting of the Court of Examiners on January 22nd :—

Butler, George Robert
Farmer, E. W. White
Gubbin, George Frederick
Harper, Charles John
Harris, F. W. H. Davie
Hatton, George Stokes
Hawkins, F. D. Cæsar
Garrard, Jacob Henry
Peck, Edw. George, M.B. Cant
Powell, Henry Albert
Winterbottom, Charles

The following were admitted on January 23rd :—

Atkin, Charles
Billiald, Richard Atherstone
Bissill, Arthur Kent, L.S.A.
Buckell, Arthur Edward
Gilkes, Malim D'Oyley, L.S.A.
Harries, Arthur John
Henty, Sydney Haviland
Knight, William
Mathews, S. R. Harvey
Palmer, John, Langford
Phelps, Philip
Phillips, L. W. Kinglake
Sers, Clement Henry
Smith, James Snowden
Towlson, Harry Joseph
Whitworth, William

**University of Durham.**—Primary Examination for Degrees in Medicine and Surgery.—The following candidates passed at meetings of the Board of Examiners, January 27th, 28th, and 29th :—

Cheetham, W. H., M.R.C.S.
Giles, B. F., M.R.C.S., L.S A.
Lloyd, G. J., M.R.C.S., L.S.A.
Mantle, A., M.R.C.S., L.S.A.
Pardington, Geo. L., M.R.C.S., L.R.C.P., L.S.A.
Porter, W. S., M.R.C.S., L.R.C.P
Roué, William Barrett
Seager, Herbert West, M.R.C.S., L.S.A.
Wills, Joseph Pearce Budgett
Wray, Charles

fOne candidate referred in botany, and two candidates referred in all subjects, will be permitted to re-enter for examination in April next.

**Association of Surgeons Practising Dental Surgery.**—The annual meeting of this Association was held on Wednesday, January the 28th, when the treasurer's report was received and adopted, showing the society to be in a highly prosperous and flourishing condition. The following Officers and Council for 1880 were duly elected:—*President:* Mr. W. A. N. Cattlin. *Vice-Presidents:* Messrs. J. A. Baker, S. Cartwright, Coleman, Salter, F.R.S., and Dr. Smith, F.R.S. Ed. *Treasurer:* Mr. Edgelow. *Hon. Secretary:* Mr. Craigie. *Council:* Messrs. E. Bartlett, S. H. Cartwright, Fairbank, F. Fox, C. Gaine (Bath), Napier, W. Ranger, and A. Winterbottom. The first dinner of the Association took place in the evening at the Langham Hotel, Mr. S. Cartwright in the chair, at which over fifty Fellows and their friends were present, amongst whom were the Presidents of the Royal Colleges of Physicians and Surgeons, Sir William Gull, F.R.S., Dr. Quain, F.R.S., Mr. Young, M.P., Dr. Andrew Clark, President of the Medical Society of London, Mr. Ransford, Mr. Lister, F.R.S., Mr. Edwin Saunders, &c.

## NOTICES TO CORRESPONDENTS.

A Superintendent.—Letter in "Defence of Private Lunatic Asylums" received as we were at press: will appear in our next.

Dr. Hastings Burroughs, Paris.—Your communication will appear on receipt of corrected proof.

Dr. Wallace.—If possible in our next.

Senex.—Kilmainham Quarter Sessions; sum not material: employ a solicitor, who will give you due notice of date. You *must* be registered

Obstetrical Society of London.—Wednesday, Feb. 4, at 8 p.m. Specimens: New Instruments, by Dr. Heywood Smith.—Moles and Fibroid Tumour of Vagina, by Dr. Herman.—Annual Meeting. Election of Officers. Changes in By-laws. The President's Address.

The Medical Society of the King and Queen's College of Physicians, Ireland, will meet to-day (Wednesday), at 8 o'clock, when the following communication is set down for reading: Dr. Henry Kennedy, on "A Case of Fatty Heart, with exhibition of the recent specimen."

Epidemiological Society.—To-day (Wednesday), at 8 p.m., Dr. Squire will exhibit Micro-photographs, by Dr. Sternberg, of the Blood in Yellow Fever.—Dr. Joseph Ewart, "On Enteric Fever in India, with some Observations on its probable Etiology in that country."

Royal Institution.—Thursday, Feb. 5th, at 3 p.m., Professor Dewar, "On recent Chemical Progress."

Harveian Society.—Thursday, Feb. 5th, at 8½ p.m., Mr. Osman Vincent, "On Congenital Talipes in the Adult."—Mr. Walter Pye, "On the present Position of the Operation of Nerve-stretching."

### VACANCIES.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary, £70, with board. Applications to the Chairman of Committee before Feb. 21.

Ballycastle Union, Croagh Dispensary.—Medical Officer. Salary, £100, with fees. Election, Feb. 7.

Hungerford Union.—Medical Officer for No. 3 District. Salary, £80, with the usual extras. Applications to the Clerk of the Union before Feb. 10.

Huntingdon County Hospital.—House Surgeon. Salary, £60, with board. Applications to Mr. P. Tillard, Stukeley Hall, Huntingdon, before Feb. 6.

Ashton-under-Lyne District Infirmary.—House Surgeon. Salary, £80, with board. Applications to the President before Feb. 27.

London Fever Hospital.—Physician and Assistant Physician. Applications, with testimonials, to the Secretary, Liverpool Road, Islington, by Feb. 7.

Middlesex Hospital.—Assistant Physician on the Staff. Applications to the Secretary-Superintendent before Feb. 7.

St. Luke's Hospital.—Clinical Assistant. Board and residence, but no salary. Applications, under cover, to the Secretary, before Feb. 12.

Steevens' Hospital.—Consulting Surgeon and two Physicians. Election, Feb. 5. (See Advt.)

### APPOINTMENTS.

Bond, C. J., M.R.C.S.E., L.R.C.P.L., Resident Surgeon to the Bedford General Infirmary.

Clubbe, C. P. B., L.R.C.P.L., M.R.C.S., Senior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

Forbes, D., M.B., L.R.C.S.Ed., Assistant Medical Officer to the Workhouse, Brownlow Hill, Liverpool.

Graham, B. G., M.R.C.S.Eng., Medical Officer to the Irvinestown Union Workhouse.

Griffith, G. B., M.B., C.M., Medical Officer and Public Vaccinator for the Carnarvon No. 1 District of the Carnarvon Union.

Hunt, H. J., L.R.C.P.L., a Medical Officer to the Harrogate Bath Hospital.

Jones, A. L., M.R.C.S., House Surgeon to the London Hospital.

Kenny, J. E., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the North Dublin Union Workhouse.

Myrtle, A. S., M.D., L.R.C.S.Ed., Physician to the Harrogate Bath Hospital.

Rendall, S. M., M.B., C.M., M.R.C.S., a House Surgeon to the Edinburgh Royal Maternity and Simpson Memorial Hospital.

Sainsbury, H., M.B., Junior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

Shapley, F., M.R.C.S.E., House Surgeon to the London Hospital.

Smyth, Dr. P., Medical Officer and Medical Officer of Health for the Stamullen Dispensary District of the Drogheda Union, co. Louth.

Somerville, W., M.D., a Medical Officer to the Harrogate Bath Hospital.

Swete, H., M.D., Physician to the Worcester General Infirmary.

Wade, J. J., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Lettermore Dispensary, Oughterard Union.

## Births.

Collins.—Jan. 28, at Chew Magna, the wife of C. Howell Collins, F.R.C.S., of a daughter.

Wilson.—Jan. 27, at Portland, the wife of Surgeon-Major F. B. Wilson, M.B., of a son.

## Marriages.

Coghlan—Butler.—Jan. 27, at Inistioge, co. Kilkenny, P. F. Coghlan, L.R.C.S.I., Kilmacow, Waterford, to Katty, eldest daughter of Edward Butler, Inistioge, co. Kilkenny.

Nicholls—Faulconer.—Jan. 27, at St. Matthew's, Oakley Square, Howard H. J. Nicholls, M.R.C.S., L.S.A., of Hailsham, Sussex, to Harriett, eldest daughter of T. Faulconer, Esq., of Hailsham.

O'Farrell—Armstrong.—Jan. 24, at Dunmore East, co. Waterford, Nicholas Sweetman O'Farrell, B.A., M.B., &c., to Emily C. Armstrong, second daughter of Captain William Armstrong, J.P., of Ballydavid, co. Waterford.

## Deaths.

Bell.—On Jan. 15, at Lhanbryde, James Nicholas Bell, M.D., Surgeon-Major, A.M.D. (on half pay), aged 49.

Gibson.—On Jan. 21, George Gibson, M.D., Surgeon, Royal Naval Hospital, Port Royal, Jamaica.

Dyer.—On Jan. 28, at 16 Alexander Square, S.W., Henry Sumner Dyer, M.D., aged 71.

Halton.—On Jan. 25, at Headfort Place, Kalls, co. Meath, Richard Joseph Halton, L.K.Q.C.P.I., aged 40.

Key.—On Jan. 18, at Edinburgh, Thos. Key, late Superintendent Surgeon, Madras Army.

Leader.—On Jan. 28, at Mill Street, co. Cork, John Leader, M.D., J.P., aged 72.

Lister.—On Jan. 26, at Doncaster, Douglas, youngest son of the late John Lister, F.R.C.S., aged 28.

Massy.—On Jan. 15, at Woodfort, Fermoy, co. Cork, Thomas Massy, M.D., aged 75.

Morgan.—On Jan. 17, at St. Giles Street, Norwich, Arthur Morris Foster Morgan, M.R.C.S E., L.S.A.L.

Naylor.—On Jan. 22, at Stockport, James Naylor, L.S.A.L., formerly of Halifax.

Owen.—On Jan. 28, at Oxford, E. R. Owen, F.R.C.S., aged 70. Friends will please accept this intimation.

Osmond.—On Jan. 9, at Thorpe-le-Soken, Thomas Edward Osmond, M.R.C S.E., aged 69.

Robbs.—On Jan. 22, at Grantham, after a few days' illness, Charles Henry Denny Robbs, M.D., aged 47.

Roe.—On Jan. 4, at Malta, Peter Mitchell Roe, L.F.P.S.G., Surgeon, Royal Dockyard, Malta.

Thom.—On Jan. 19, at Brampton, Cumberland, Alex. Thom, L.R.C.P.

Yate.—On Dec. 8, at Shanghai, shot by misadventure, Henry W. Yate, M.R.C.S., youngest son of Frederick Yate, of Godalming, Surrey, aged 23.

## LARYNGISMUS STRIDULUS.

By W. H. DAY, M.D.,
Physician to the Samaritan Hospital for Women and Children.

*(Continued from page 80.)*

WHEN the disease is once established, a violent fit of crying, or any attempt at swallowing, or sudden movements will bring it on. Changing the nurse, or giving improper food will invite an attack in a delicate child, especially if it is the subject of convulsions, between which and laryngismus there seems to be a close connection. (*a*) (*b*) The following is a fatal case in point. On the 27th of January, 1875, I was requested to see the male child of a lady residing in a large and well-arranged house in the west end of London. He was five months old, and was born strong and healthy. A wet-nurse was procured for the first three months, when she left, as her milk was supposed to disagree. On examination I found it perfectly healthy. The child was fed with milk and Robb's biscuits, and for a few days before my visit, "Chapman's wheat flour" was substituted, which appeared to agree. The child had been successfully vaccinated on the 25th of December from a healthy infant, and from this time the mother thought it had become pallid and flabby. The general condition seemed, however, satisfactory, and the pallor was probably due to his being shut up in the house. There was a large family of children, but none of the others had ever suffered from a similar affection, or from any illness of importance. On the day previous to my visit the child was seized with what the nurse termed croup, being unable to get his breath for some moments, the attack ending in a crowing inspiration and a wheezing cough. The child was irritable and restless, and could not obtain sleep ; the bowels were sluggish, and the motions dark and offensive. I prescribed a powder consisting of bicarbonate of soda and rhubarb every night, and a mixture of bromide of potassium and sal volatile three times a day. The child to be fed on cow's milk only.

Jan. 28th. 9 a.m.—I received a note to say that the child had had four convulsions during the night. The nurse had carried him in her arms all the night, and if she attempted to put him down he could not breathe. The seizures were marked by fixed eyes, pallor of cheeks, darkness of the lips, and a convulsive movement of the body. Some of these attacks ended in a long crowing inspiration. When I approached the child at my visit he seemed almost electrified, starting in the nurse's lap, and looking dreadfully alarmed. There was some coryza, with running of the nose and eyes ; the skin was moist and warm ; temp. 100°, pulse 156 ; respirations 36, noiseless. At 3.30 a.m. the bowels had acted well, the motion being of a light yellowish ochrey colour, with slimy discharge. The food to consist exclusively of two parts of cow's milk, and one of sweetened barley water. In the shape of medicine a mixture was ordered consisting of citrate of potash, bromide of potassium, and tincture of henbane.

12 a.m.—Sleeping tranquilly, but on being touched he started convulsively ; there had been one attack of crowing since my last visit. At 5 p.m. he was sleeping, and there had been no return of the crowing ; at 9 p.m. he was resting in his mother's lap ; the face was calm and peaceful ; the skin cool ; pulse 120.

29th. 9 a.m.—The bowels had acted moderately three times, but the child was continually drawing up his legs and crying, as though he had stomach-ache ; there had been no sickness and no convulsion. He was rather pale ; pulse 120, respirations 32 ; the skin was cool, and the breathing, as ascertained by putting the ear to the

---

(*b*) "The occurrence of general convulsions in connection with laryngismus, indicates that the morbid action extends to and involves some larger group of nerve-cells than in the local spasm, probably either the whole of the medulla oblongata, or the corpora quadrigemina also"—"On Functional Nervous Disorders," J. C. Handfield Jones, M.B., 1870, p. 631.

back of the lungs, was unembarrassed; the pupils were normal, and he looked round intelligently. I considered he was likely to recover. I went down stairs, and just as I had reached the hall I was summoned again, when the mother handed me the child, whose lips and face were now dark, his limbs relaxed, and he was apparently dead. He did not breathe afterwards, and death must have taken place in a minute from asphyxia.

"Cases are sometimes to be met with which are of a more chronic character, and where there is no immediate danger to life.

Case 2.—On April 12, 1875, a female child, fifteen months old, came under my care at the Samaritan Hospital, which had suffered more or less from laryngismus ever since she was six months old. The child was rickety, with the strumous diathesis strongly marked, the head was large, and the anterior fontanelle wide and prominent; the veins were distended over the scalp; the face was pale and flabby, and there were only six teeth. Three months before I saw the child she had had convulsions, which continued more or less for some time. The child was often breathless, and the respiration habitually accelerated, and frequently croupy. If excited in any way, as playing with other children, the attack was certain to occur, and so bad was it that her mother thought she would sometimes die in it, as her face became dark and purple. Sudden changes of weather, as from heat to cold, or the reverse, were certain to invite a seizure. It sometimes came on in the night. The mother stated that she had suckled the child, having had plenty of milk, but this was certainly not so, as her health was delicate; but till within a short period she had scarcely ever given the child any other form of nourishment. The child made a fair recovery from the fits, but remained delicate when I saw her a year after first coming under treatment.

Death may take place (1) from asphyxia, as in the first case related, where the cavities of the heart are full of blood, and the lungs engorged; (2) from cerebral congestion and serous effusion; (3) from exhaustion, and failure of the vital powers. "The sudden death, which is by no means uncommon in this disease depends, I conceive, on the transmission of irritation along the cardiac fibres of the vagi to the heart, which is then arrested in its action, just as when the pneumogastrics are strongly galvanised." (*a*)

*Pathology.*—The disease appears to depend primarily on irritation of the pneumogastric nerves, which is provoked by disease of the cervical or bronchial glands, or by irritation of the fifth nerve, as from teething, or by disorder of the stomach and intestines.

The irritation is propagated to the inferior or recurrent laryngeal nerve, and the muscles of the larynx are thrown into spasm. The larynx is entirely free from inflammation, and there is no lesion of its mucous membrane. It is a purely neurosal affection, and whatever anatomical changes may be found after death are in most cases consequences, rather than causes, of the seizure. "It seems rather to be an independent affection of the par vagum, or of its recurrent branch, due either to pressure along some part of the course of one of these nerves, or to centric irritation at the root of the vagus; or else we may be compelled to regard its exalted sensibility as a reflex phenomenon arising from excitement of some other nervous trunk. In most cases the pathogeny of this disease is obscure." (*b*) Dr. West likens the disease to hysterical fits in the female, and says that both affections are most common when the processes of life are most active. (*c*) In some cases effusion into the ventricles, congestion of the brain, or even tumours in the cerebral substance have been found after death. Tubercle of the lung and bronchial congestion have been also noticed. Still morbid appearances are sometimes entirely absent.

The *diagnosis* from croup is given in the chapter under that heading, but it may be here stated that the suddenness of the seizure and its departure, the normal breathing in the intervals of the attacks, and the absence of fever and inflammation, are the distinguishing features of this peculiar complaint.

As the disease increases there is a disposition to general convulsions, whilst these occur only at the last stage of croup. The crowing sound is not unlike that of whooping-cough, but in laryngismus there is no expectoration, nor vomiting, nor catarrh in the strict sense of the term.

The *prognosis* may be considered generally favourable in slight cases, when the seizures are not frequent, the health tolerably good, and there is no complication. When the case is mild, and the crowing comes on at long intervals, it usually yields to judicious treatment. Still, the disease is always to be regarded with anxiety, and especially, if severe, from the liability to cerebral complications, convulsions, or sudden death. "Out of fifteen cases of which I have kept a record, eight died. *Rilliet* and *Barthez*, out of nine cases, and *Herard* out of seven, observed in each only one single instance of recovery." (*a*)

*Treatment.*—The first indications are to remove all exciting causes. If the bowels are disordered they should be set right as soon as possible by proper aperients, and healthy digestion promoted. If the child has taken a heavy meal, or indigestible food, an emetic may be advisable; and should the gums be swollen, and dentition appear to invite the complaint, they ought to be scarified. The child should occupy an airy apartment, and noise and excitement be precluded. If seen during the paroxysm it should be kept in an upright position, and the windows opened, so that it may be encouraged to breathe. In severe cases, especially if a convulsion threaten, it may be immersed in a warm bath, whilst cold water is sprinkled at the same time over the face. Dr. Morley Rooke recorded a case of laryngismus stridulus in a child nine months old, where occlusion of the larynx during the fit produced symptoms like those of "a recently drowned person." The little patient "showed no sign of life" when first seen in the seizure; the lips were blue and swollen, the face a livid grey, and the eyes half-closed and glassy. Dr. Rooke thrust his finger between the teeth to the fauces, when the child gave a short heave and a gasp; on repeating the movement inspiration took place, and in a few more seconds breathing ensued. On two more occasions when occlusion of the larynx was equally severe, a similar manœuvre brought round the child. This is a mode of treatment well worth bearing in mind when the child threatens to die from spasm of the glottis. The cure was completed by bromide of potassium, which was taken for eleven months. (*b*)] Dr. Wardell also points out the beneficial effect of "rotating the finger in the throat" in these cases; it induces an attempt to vomit when the laryngeal muscles become relaxed, and air is admitted into the trachea. He says it is the first thing to be done, and he has seen it succeed when death seemed imminent." (*c*)] In extreme cases, where death threatens from asphyxia, the operation of tracheotomy should be employed. The inhalation of chloroform has been recommended in some cases, but then its influence soon passes off, and it cannot be said to have any curative effect. When there is much restlessness, and the child can obtain no sleep, the excitability of the nervous centres must be calmed, and for this purpose small doses of morphia may be cautiously employed. In the intervals of the seizures the bowels must be kept freely open, so as to remove all sources of irritation that might sympathetically excite spasm.

Among the chief drugs are belladonna, in the form of

(*c*) Ibid, p. 474.

extract or tincture, which sometimes has the effect of diminishing the glottic spasm, but in most cases it fails altogether. Bromide of potassium is very serviceable given with citrate of potash, sal volatile, or quinine, according to the peculiarities of each case. (*a*) Carbonate of ammonia, henbane, bark, and mild preparations of iron, as the ammonio-citrate, or the syrup of the iodide, are remedies to be selected. If the child is strumous and rickety, or in any way delicate, cod-liver oil is invaluable. It is a remedy which ought to be persevered with, as by improving the general health we may so keep off the disease.

Diet is of great importance, and, when carefully selected, the disease may disappear without drugs. If the child is fed at the breast it is sometimes advisable to change the nurse, or to give cow's or ass's milk. If older, the food must be light and nutritious, and given frequently in small quantities. The clothing should be warm, and if the child is not too ill he ought to be taken out in the open air daily.

◆

## ACUTE MENSTRUAL GOITRE. (*b*)

By E. H. BENNETT, M.D., Ch.M., F.R.C.S.I.;
Professor of Surgery in the University of Dublin; Surgeon to Sir Patrick Dun's Hospital.

THE earliest—and indeed the most complete—description of the variety of goitre of which I am about to record examples, is given by J. L. Petit (1740). Subsequent writers have most of them omitted all mention of the affection, while others have only made such allusion to it as to prove the scantiness of their knowledge regarding it. One great authority—Virchow—refuses even to admit the disease into the class of goitres. He says :—"Every one is familiar with the temporary swellings which appear during menstruation (lunar or menstrual goitre) and during pregnancy, but these are not goitres at all." His statement is contradicted, so far as the variety which occurs in pregnancy, by the treatises of M. Guillot, M. Ollivier, and most recently by Mr. Lawson Tait, who have all written specially on this subject, one of them—M. Ollivier—dividing these cases into three distinct groups. In the classical descriptions of Graves, Stokes, and Trousseau, accounts are given of the sudden development of vascular bronchocele, but in the cases I am about to record the characteristic features of vascular bronchocele were entirely absent ; nor, indeed, do they appear to have been present in the cases referred to by Petit. His attention was apparently forcibly directed to the subject of goitre, particularly that of pregnancy, for one of his leading cases is that of his own wife, whose disease, after causing him much anxiety, and for a long time, yielded at the end to his own surgical skill.

He says, writing of the goitre of pregnancy and of menstruation, "it often happens to women after their confinement, in consequence of the violent efforts that they have made in giving birth to their children, that the thyroid gland swells, and forms a tumour more or less marked. This disease occurs sometimes in girls who have not as yet menstruated, or in whom the natural evacuation is established with difficulty. In both one and the other, these tumours occasionally disappear by attention to diet, by attention to general and local remedies, &c. I have seen these tumours disappear on the establishment of the menstrual function."

Very different is the modern statement of Billroth : "Goitre cannot be regarded as a product of inflammation, as it never spontaneously retrogrades, suppurates, or shrinks into a cicatrix." Hasse, writing on hypertrophy of the thyroid gland, says : "Both lobes of the gland, and even the middle one, swell, so as to encroach equally on each side, against the trachea and the vessels of the neck. Serious accidents may arise where the lateral lobes enlarge posteriorly, and tend to form a girdle round the trachea. Simple hypertrophy of the thyroid gland is almost wholly confined to youth, and is frequent about the age of puberty in both sexes, more so, however, in the female. Alternations of increase and decrease are especially apparent in this kind of bronchocele, enlargement being most conspicuous at the approach of the menstrual period." I cannot find further information in the recognised authorities, most are blank searches. The facts of my first case are these :—A healthy girl, between fifteen and sixteen years of age, born and bred in Dublin, was admitted about midday on 12th October, 1878, into Sir P. Dun's Hospital, suffering from intense dyspnœa. The presence of a bronchocele of considerable size, and its evident relation to her dyspnœa, rendered the diagnosis easy. However, to guard against possible error, I examined the larynx with the mirror, and recognised at once that there existed neither foreign body nor spasm, and again, no œdema. The mucous membrane was livid, but not distended or swollen. The urgent distress made the exploration of the deeper parts of the trachea not advisable. Nothing could at the time be learned of the previous history from the patient, nor, indeed, from those who brought her to hospital, so much was the attention of all taken up with the impending danger to her life.

After her recovery from this attack, and the tracheotomy which it demanded, I got from her in writing, a short account of her disease. She says, "I will be sixteen years old on the 19th of next March ; my parents and two brothers are healthy ; I am the only daughter and the only delicate one of the family. A year ago the wheezing commenced ; did not feel uncomfortable in any way, unless when doing a little household work or walking quickly, then the wheezing could be heard outside the door. Sometimes the tumour would grow larger, and then go back. I have noticed it specially from Sunday to Sunday, as one day my dress would fasten round the neck, and next Sunday would not. In August last my neck got more swollen, and has remained so ever since. I did not mind it much, as I thought it was a cold. I had been with Dr. H—— on the Tuesday before I came here. He ordered iodine to be applied twice a day, which made my neck a great deal worse." Of course the doctor gets the benefit of the doubt, and is made a scapegoat for the disease. We learned that an abortive attempt at menstruation had occurred about six months before the patient's admission, and that, although in all other respects fully developed, this had been the only sign of establishment of the function. The degree of dyspnœa made me confident that nothing but operative relief would be obtainable. I resolved, however, to try the effect of free vomiting induced by tartarised antimony, with hot stuping over the neck and chest. I wished to obtain the assent of the girl's parents before operating, an assent that could not be obtained at once. So a fair interval for the trial of the remedies we most rely on was obtained. No relief, rather an increase of suffering, resulted. Late in the afternoon, with the assistance of Mr. Colles, and Dr. T. E. Little, I proceeded to open the trachea ; so far towards the sternum did the tumour reach, and so completely did it fill the depression above that bone, it was clearly impossible to attempt an incision to reach the trachea below the isthmus of the thyroid. There were none of the characters of a vascular bronchocele present, no large arteries to be felt, no murmur or thrill, but the bulk of the tumour projected below, and in the middle line, and the trachea could not be reached, except through the middle of it. I could just feel with certainty the resistance of the cricoid cartilage by passing my finger from above behind the tumour. A few whiffs of chloroform were given, and rapidly took effect. I then cut down for the cricoid cartilage as rapidly as I could without wounding

the capsule of the tumour. Except for the bulging of the tumour upwards into my incision, I met no difficulty, no vessel of importance. I could not use the tenaculum to fix the trachea or cricoid cartilage, so I was forced to open the air passage without this great help. The crico-thyroid membrane and the cartilage being divided, I tried to open the incision with Chassaignac's instrument, but this failed completely, as the tumour projected, so as to prevent the instrument being placed vertically to the axis of the larynx. I at once put the handle of a scalpel in the wound, and turned it half round, so as to keep the edges of the tracheal incision asunder, but although the girl made faint efforts to breathe, air would not enter freely. There was not sufficient blood to impede the air spilt into the air passages, and as the pressure of the tumour seemed to be rendered more active by the division of the tissues, I determined at all risks to extend my incision downwards. I passed a probe-pointed bistoury on my finger into the trachea, and divided it for some distance behind the tumour. Although these manœuvres had nearly completed the apnœa, a rush of air followed the withdrawal of the knife, and some small blood clots were expelled. A tube of fullest size was introduced, but some moments spent in active stimulation, and of efforts at artificial respiration elapsed before breathing was re-established. Presently reaction followed, and the girl's relief seemed complete. In two hours' time, on visiting her, I found that the dyspnœa had returned almost, to my idea at least, as badly as ever. It was evident that the tumour was pressing hard against the trachea below the tube, but the girl begged to be let alone, urging that she was quite relieved. She evidently feared to face any further suffering. In two hours more her condition was quite as alarming as it had been on the operating table, and she now yielded to my offer to relieve her. I withdrew the tube, and passed a full-sized silver prostatic catheter into the trachea, and availing myself of its long curve, passed it towards the chest, meeting some slight obstruction. As its point passed down beyond this, the air entered with a rush, and all was well again. On a second instrument of the same size and curve, I measured the length of the first instrument outside the wound. Here I cut the instrument across, and made a couple of holes at its sides to enable me to secure it. I then put the tube so extemporised, in the place of the catheter, in the wound, and let the patient go to sleep, which she did with a will. Finding the length and curve of the tube suit, I should probably have continued to use it, but that its eyes appeared too small, becoming choked easily, and again the threads used to fix it caught the mucus as it was expelled. I at once had a tube of the size of a full tracheotomy tube, modelled after the plan of the catheter soldered to a tracheotomy tube. The size of tube and the thinness of its material made a much larger passage for air and mucus, while the eyes were easily made of much larger opening than in the catheter. Considering the length of the tube it was clear that its extremity must reach, when in place, to the bifurcation of the trachea or very close to it. I thought it safe for this reason to close the end of the tube, as a sharp edge so low in the chest was likely to be a source of grave risk should it cause ulceration. Working in this way I got an efficient tube which allowed a free and safe respiration. I attempted to shorten it, but only such as I now exhibit, 5⅜ inches long, would pass beyond the the constriction which impeded respiration. A second tube made to match the first put my patient in a most comfortable condition. After a short time she improved in health, began to menstruate regularly, and with this change a noticeable diminution of the bronchocele occurred. The circumference of the neck fell from 15¾ in. measured over the tumour, to 12½ in. In January I saw these changes so fully established, I considered I should try to get rid of the tube. I kept various devices in the wound, which stopped it so as to accustom the larynx to do its full work, and finally finding no contra-indication I allowed the wound to close. This it did rapidly until only an ordinary probe would pass. Just when this point was reached the dyspnœa recurred and I was obliged to dilate the wound, finally dividing it with a probe-pointed bistoury, and to reintroduce the tube. This job was almost as difficult as the original operation. The girl left hospital on February 22, 1879, wearing her tube and educated to introduce it herself and to change from tube to tube daily. I readmitted her on 25th of June, at her own request, to repeat the trial to give up the tube. Much the same train of events followed; the tube removed; the wound allowed to contract, and finally to close. Then a week of breathing entirely by the larynx, ending in an attack of dyspnœa, brought about apparently by the deformity of the trachea, which prevented the escape of mucus from the bronchi. Again, a troublesome job, and the tube was reintroduced and remains, the girl in perfect health general and menstrual, and free from visible goitre.

A short description gives the facts of the second case.—A healthy girl of 15 years of age, who had had one imperfect menstrual discharge, was admitted under Dr. Purser's care to Sir P. Dun's Hospital, in the end of April, 1878, suffering from a very prominent goitre. She stated positively that it had not appeared, or been observed by any symptom, until six weeks before her admission, it appeared about the time of the first signs of menstrual discharge. She suffered from paroxysms of dyspnœa, but her ordinary breathing was easy, and her voice natural. After she had been some five weeks in hospital, Dr. Purser finding her tumour rather increasing in spite of treatment, and her attacks of dyspnœa being more urgent, asked me to see her with him. We saw her just at the close of an attack of dyspnœa, which had alarmed the clinical clerk and nurse. I found, however, that her breathing was not such as would suggest a tracheotomy, while her lips and cheeks were florid. She had no depression of the ensiform cartilage in inspiration; in short, her paroxysm was over, and did not appear to have been urgent. Her manner was quiet and cheerful and quite free from hysterical excitement. I ascertained the following day that the menstrual discharge had come on, and I expected from the experience of the previous case that relief would follow. In a few days, on the 24th of June, at Dr. Purser's request, the girl was transferred to my ward. On the morning of the 25th on entering the ward I found her asleep, lying with the head thrown back, breathing easily, with a clear florid lip; in fact, but for her bronchocele and her somewhat forced attitude, the picture of health. Unwilling to disturb her, I left the ward, and afterwards, about 11·30 a.m., passing its door on my way out of the hospital, I saw her sitting in bed, laughing. I went and talked to her, cheered her by telling her that I did not contemplate any operation as necessary. I went on my way and she dressed and went upstairs to see the nurse of the ward she left the evening before. She was presently seized with dyspnœa, was laid on the floor, and the resident staff were soon with her; in less than ten minutes she was dead. Meeting a messenger sent after me in haste, I returned to the hospital in a space of time not more than half-an-hour from my leaving it, and found that she had been dead already some minutes. I could make no post-mortem examination. Of this tumour I can only say that it, as the previous one, wanted any sign proper to a vascular bronchocele.

Such, then, are the facts of these two cases, closely similar except in issue, while one at least shows the truth of Petit's description in the disappearance of the tumour as the menstrual function is established.

◆

It is generally understood that the Duke of Abercorn will be appointed Chancellor of the new University of Ireland.

# DESCRIPTION OF DIFFERENT VARIETIES OF SKULLS AND OF HUMAN REMAINS REFERABLE TO THE TENTH CENTURY, OBTAINED DURING THE RECENT EXCAVATIONS OF A LARGE SEPULCHRAL MOUND NEAR DONNYBROOK, Co. DUBLIN. (*a*)

By WILLIAM FRAZER, F.R.C.S.I., M.R.I.A.

A QUANTITY of human remains were discovered in the vicinity of the celebrated village of Donnybrook early in the month of October, 1879. With these there were mixed the bones of some of our usual domestic animals, which were identified as belonging to a cow of small size, a young calf, sheep and pig bones, and the lower jaw-bones of a large dog, probably a wolf-dog, certainly not a wolf. They were obtained on the grounds that are marked in the Ordnance maps as "Mount Errol," lying to the south of the recently-formed Aylesbury Road, on the field that adjoins Seafield Terrace. An old roadway that is now disused and closed up led along one side of the field, and from this a well-known foot-path went towards Merrion.

The discovery was made owing to necessary excavations for building purposes, and I am indebted to the owner, Mr. Thos. Wardrop, for the ample opportunities I enjoyed for investigating all the circumstances under which this remarkable find was discovered.

In the centre of a grass-covered field, underneath a slightly elevated mound of circular form, lay a great multitude of human skeletons—in fact, several cart-loads were removed and re-interred within Donnybrook churchyard. They lay piled over each other, so far as could be ascertained, over the whole extent in three superimposed layers closely packed together, the lowermost stratum rested upon the surface of the original tough yellow clay soil; into this some of the bones had sunk slightly, becoming imbedded in it, but there was no indication of grave or any excavation for purposes of interment, properly so-called. In the course of time, as decay advanced, these three layers of human bodies had become reduced to a stratum not exceeding sixteen inches in depth; over this had been placed as a covering about twelve inches thick of clay, and in fresh sections it was easy to distinguish this layer from the undisturbed original soil; above all was resting eight inches or so of firm grass sod, that appeared never to have been disturbed or ploughed. I ascertained by measurement that the entire of these slain bodies, with few exceptions, were resting within a circle of fifty feet in diameter, and the total transverse width of the tumulus or clay mound did not much exceed one hundred feet; within this limited space were gathered into a heap possibly upwards of five hundred human skeletons.

The attention of the workmen in Mr. Wardrop's employment was first attracted by their discovering one complete human skeleton placed almost due north and south, its head being to the northwards. This was found outside of and a few feet distant from the great gathering of bodies. It was described to me as having bones of very large size, and at its sides were lying a double-edged iron sword and the rusted head of an iron spear, which were preserved and given to me. At the feet of this man there were found two other skeletons of persons of smaller size, probably women, but all these bones got mixed up with other remains, soon afterwards discovered, and could not therefore be identified. With the sword and spear, I got a skull also given to me that had a sword cut on the frontal bone, and I believe this to be the skull of the first-mentioned body.

The sword is an iron weapon with broad double-edged blade, having a plain transverse iron hilt and pommel. It corresponds in every respect with the shape of the sword which was used by Scandinavians, Danes, or Viking invaders. Examples of such swords are preserved in the Scandinavian museums. The King of Denmark presented one of them to the Royal Irish Academy, and they also turn up occasionally in different parts of Ireland, and are to be found in different museums here. But this special weapon possesses features of peculiar interest, for its hilt and pommel are both richly decorated with an inlaid pattern, worked into the steel, of gold and silver ornamentation; it is thus unique in so far that no other similarly ornamented weapon has been, up to this time, ever found in Ireland, and it corresponds with the celebrated swords we read of in Northern legends, that were borne only by Danish commanders of high rank or distinction. The iron spear-head, likewise, is a recognised Danish form of this weapon, and it still displays on its rusted surface portions of human bone adhering to the rust. More recently three iron arrow-heads were picked up close to the same spot, and also a rude dagger-blade of iron. In the course of the excavations two bronze pins were procured; one had an ornamented top, the other was of the well-known Irish type, with a ring at its upper part. A simple bronze ring was also found upon the finger of a female skeleton, and two iron rings of larger size were also obtained; one of these was taken off from the upper part of the humerus of a girl, which it encircled.

In the classic work upon "British Crania," published by Thurnam and Davis, we have a discovery of much interest recorded that was made at Larne, in the North of Ireland, about November, 1840. In this case a skeleton was obtained buried in a similar manner to the one I have described. The body had been superficially interred without grave or excavation, and covered with soil; at its side lay a spear and sword exactly resembling those I have described, but the sword had no trace of ornamentation. A bronze pin with a ring at its upper part was also found. These were all described by Mr. J. Huband Smith in the Proceedings of the Royal Irish Academy, and the weapons were subsequently further examined and identified by Prof. Retzius as undoubted examples of Norse weapons, and the skull as that of a Norseman. The distinguished Danish antiquary, Mr. J. J. A. Worsaae, likewise claimed the sword and spear as distinctive of Scandinavian arms, and he referred the Larne interment to the period of one of those piratical incursions made by the Robber Vikings to Ireland about the 11th century. In fact, he ascribed it to the period of a battle fought between the Irish and the Orkney Jarl Einar in the early part of that century.

When the excavations advanced southwards into the mound as already mentioned, we ascertained that a great number of human skeletons were contained within it. It included the bones of men and women and children of every age, from the unborn infant to advanced senility, evidenced by finding toothless jaws with absorbed alveolar tissue. Having one day gathered for the purpose all the adult sacral bones that had turned up for some hours of digging, they were examined carefully and measured, and it was found they represented both sexes in nearly equal proportion. The discovery of such quantities of female bones, and of those of children and aged persons, at once showed this must have been a massacre, and not a battle. All the other circumstances observed corroborate this view. Professor McAlister obtained two fœtal femora still resting undisturbed within the cavity of a female os innominatum. This was clearly the remains of a fœtus in utero. I got other bones representing early pregnancies, and have preserved the lower jaw bone and half of the os frontis of an infant at about the seventh month of intra-uterine development, as also the lower jaw of a recently born child.

There were numerous remains of young children, aged from one to nine years; their lower jaws presented every stage of infantile dentition; and from this onwards to youth and perfect maturity, until the last molars are found completely developed, a large series were gathered together. The teeth, as a rule, are found to be unusually strong and healthy. But toothache was not altogether unknown, and sufficient examples of diseased fangs, and even a perforation of the jaw bone from abscess at the root of a tooth, could be recognised. The worn-down

---

(*a*) Read before the Surgical Society of Ireland.

condition of the grinding surfaces of these teeth was most remarkable; they show an amount of attrition altogether unknown at present in the British Isles; of course this is best seen in mature jaws, and during advancing life. Excessive attrition is common to all races that use food requiring a considerable degree of mastication; thus it occurs both in those who employ corn ground in hand-querns, in which it becomes mixed with more or less of the sand from the mill; and it has likewise been noticed in tribes that live upon fish diet almost exclusively, as in the neighbourhood of Vancouver's Island. There were further, as I have stated, several jaw bones that had belonged to persons of considerably advanced age, where the teeth had almost or altogether fallen out, and in which the bony alveolar tissue was absorbed, and had disappeared both in lower and upper jaws.

Many of the bodies lay heaped together as if thrown on top of each other in promiscuous groups; but as the excavations were extended towards the east side, Dr. McAlister and I found two rows of bodies lying side by side, placed east and west, on the surface of the soil, the feet of one layer resting upon the shoulders of the preceding skeletons, and several of these skeletons were ascertained to be headless. The heads of some others lay at an appreciable distance from the rest of the bodies, and about this part of the excavation we likewise got groups of human heads collected together, quite separated from their bodies, and put into heaps. Four such groups were uncovered, all arranged along a line north and south, and not far distant from each other. I carefully examined all the heads contained in the last discovered group, which consisted of eight crania. They belonged to persons of advanced age, for the sutures were in process of progressive obliteration, and they had all been injured by perforating fractures of the skull of peculiar character as if caused by some sharp-pointed weapon. After the heads were cut off they must have received rough usage, for all the face bones were broken, so that I could not secure one perfect skull out of the entire. One of the lower jaw bones had also been fractured. I found in another skull not in this group that the nose and part of the upper jaw bone had been cut off.

Amongst the bones which I obtained there are some that appear worth describing, either for their size, or because they present evidences of diseased conditions. The vertebræ and some of the bones of a man were dug up who must have, when living, been of exceptional size. The vertebræ are wider—not thicker—than those preserved in the Anatomical Museum of the Dublin University, belonging to the famous Irish giant, O'Brien, so their possessor was probably a person of great bulk.

Platycnemic tibiæ were also found to be very numerous. Tibiæ of this character are ascertained to be of frequent occurrence in French and English graveyards, referable to dates from the fourth to the tenth century. Their presence and frequency in the Donnybrook find affords us strong additional corroboration as to the early date to which they must be referred. Platycnemic tibiæ were first observed in the family buried at Cro-Magnon in Perigord, referred to the ancient Stone Period, or that when the reindeer roamed over the forests of Southern Europe. From this time they are noticed extending through the ages when polished stone weapons were employed; and out of 200 tibiæ collected near Paris in cemeteries belonging to dates anterior to the tenth century, 5·25 per cent. were of this platycnemic form.

There were some good specimens obtained of bones affected with chronic rheumatic arthritis. The polished eburnation of the head of a femur, its peculiar shape and osseous growths, afford unmistakeable proof that its former possessor suffered from this painful affection, so well described and illustrated by the late Robert Adams. The number of bones thus affected showed that this disease was not uncommon.

There is also a remarkable specimen of depression observed upon the upper portion of the outer surface of a frontal bone. This appears to have resulted from long-continued pressure caused by the growth of some external tumour, most probably a congenital wen of considerable size, or at least one that must have become developed early in the individual's life.

The results noticed of an old fracture of both the tibia and fibula at the upper third are well worth describing. The oblique direction of the fracture is seen, and an enormous mass of callus has united the fractured bones into one, obliterating the interosseous space. The upper end of the tibia is expanded and hollow, and was, it is probable, the seat of a local necrosis.

Two sacral bones of females were picked up, both of which are very crooked, one half being less developed than the opposite, and the coccygeal termination, instead of being in the medial line is at the side. These appear due to some injury sustained in early life.

Portions of the skull of an idiot were likewise obtained; they possess an unusual amount of interest. The frontal bone shows the cranium to have been that of a young person. The orbital openings are placed on a different level, the right orbit being considerably more elevated than the left. The bone itself is imperfectly developed, the entire right half being smaller than the left, and a similar condition is recognisable in the occipital bone. A face such as this individual must have possessed is delineated in Dr. Robert Smith's work on "Fractures and Dislocations." It is described as an example of the rare congenital dislocation of the lower jaw, and on looking at his plate and comparing it with the frontal bone now shown it is impossible not to be struck with their identity of aspect. The subject is so fully worked out by Dr. Smith that it is unnecessary to do more than to refer to his accurate description. He considered this malformation so rare that in addition to his own case he records only one other example briefly noticed by M. Guerin. The case which Dr. Smith published was that of an idiot who died in the lunatic asylum at Island Bridge; the details are consequently most perfect. I regret to say that neither the lower jaw nor any bones of the face are forthcoming of my specimen which I picked out of a mixed heap of bones thrown together, so that although there is every probability of its being an example of the very rare congenital luxation of the lower jaw, we have only the frontal and occipital bones preserved and a portion of the parietal.

Another idiotic skull, that of a microcephalus, is in perfect preservation. It has a fairly elevated forehead, is of neat rounded shape, but the upper jaw is decidedly prognathous, the lower jaw being small and of moderate development; it resembles in miniature in every respect the class of skull which I consider of Celtic or Irish type, and of which I possess several fully developed examples from this find, but it measures in circumference only 438 millimetres. The arrest of its development has not been caused by synostosis, for the sutures are unclosed and perfect, and the age of its possessor is easily calculated, as the third molars are still in process of becoming developed. M. Broca refers to this class of demi-microcephales all non-deformed skulls of males that possess a horizontal circumference of less than 480 millimetres, and of females those under 475 millimetres. If belonging to Europeans they should possess an internal capacity below 1,150 cubic centimetres. This condition of general or partial arrest of cerebral development will commence during the stage of intra-uterine existence, and it therefore constitutes an important anatomical variety of idiocy. The well-known Hottentot Venus, of which I am able to exhibit a portrait drawn to scale, who was exhibited as a show in different parts of Europe several years ago, and whose skeleton is preserved in a Parisian museum, was an example of this idiotic demi-microcephale. Similar skulls are occasionally to be noticed in all our large asylums for the insane and for idiots; and the Aztec children, so-called, who were shown here a few years since, were specimens of microcephalic idiots with dwarfed bodies.

One portion of a skull of unusual thickness was obtained. In some parts it is almost one-third of an inch thick, measuring 15 millimetres exactly. This appears to be a natural and healthy bone, the thickening being caused by no disease whatever.

In considering the shapes of the skulls obtained that belonged to adults for classing them, I have selected out of a large number three specimens which will illustrate the three great divisions of crania which are usually described. Of these No. 44 will represent a dolichocephalic skull, No. 21 an intermediate mesaticephalic form, and No. 22 is brachycephalic.

These classifications, which depend on the relation or ratio that the antero-posterior diameter will bear to the transverse measurement of the skull at its widest part, is calculated by the formula $\frac{\text{Trans. diam.} \times 100.}{\text{an. post. diam.}}$, but such calculations are facilitated by the excellent tables of Prof. Flower, published in the last catalogue of the Museum of the Royal College of Surgeons of England. The index varies from

750 and under for dolichocephali,
750 to 800 for mesaticephali,
800 and upwards for brachycephali.

Now the cranium No. 44 affords us an index so low as 704. This is an exceptionally low result, for the skull of the average Australian savage reaches 71·49, and even the Hottentot amounts to 72·42.

No. 21, the mesaticephalic skull, is found to possess when measured an index of 754; this corresponds with the skulls of the Dolmen builders, and that of the Ancient Egyptians. It also corresponds exactly with the index ascribed by Messers. Thurnam and Davis to the ancient Irish skull. From several considerations I am led to believe this is a typical Celtic or Irish cranium.

But on examining the skull which I first obtained, No. 22, and which, I believe, was that interred with the sword and spear, having the deep sword cut in its frontal bone, the index rises to 833; this is, therefore, a good specimen of a dolichocephalic skull, and it corresponds in its measurements with the skulls belonging to the Croat, different German tribes, and the Finlander. I believe its original possessor was one of the mixed people, who originally came from the shores of the Baltic, and whom we know in Irish History as Pirate or Black Danes.

So far as the general facies is concerned, I think we may safely recognise two different and distinct types. One of these is straight faced or orthognathous; the other possesses a projecting upper jaw, which produces a prognathous appearance. There is no difficulty in distinguishing well-marked specimens of both forms, but some appear with intermediate features.

The skull marked 19 is an example of the orthognathous face,

22 is intermediate,
21 is prognathous.

The little microcephalic skull, as I have already stated, is likewise prognathous. The degree of forward projection of the upper jaw in any skull is ascertained by obtaining the alveolar index, the formula for which is $\frac{\text{basialveolar length} \times 100.}{\text{basilar nasal measure.}}$. Whenever the ascertained index ranges below 980, the face must be classed as orthognathous. An index ranging from 980 to 1,030 is mesognathous, and all above 1,030 fall into the class of prognathous individuals.

When these typical skulls are arranged beside each other, it is easy to see the great and striking differences they present in form, and in the aspect of their faces.

In presenting this brief survey of the leading features of the Donnybrook discoveries, it appears unnecessary to enter more minutely into particular descriptions. I think we can amongst these skulls recognise some which fall under the Scandinavian type of Thurnam and Davis, and that, therefore, will correspond with numerous examples of people still existing in our own land; in Scotland, and in the mratiime districts of the East of England, where Danish settlers planted their numerous colonies. To quote the words of these accurate observers: "The skull is small and regular, has a long slender elevated aquiline nose, closely corresponding with such as prevails in the northern counties of England where Scandinavian blood predominates. A narrow, long, orthognathous face, an upright square forehead, yet neither decidedly broad nor high, having a frontal suture, a long oval outline in the vertical aspect, with distinct parietal tubers, a globose tumidness in the supra-occipital region, and a large foramen magnum."

The lower jaw belonging to this class of skull is distinguished by its massive structure, square outline, and strong everted angles. The lines for muscular attachment are always prominently developed; the chin square-shaped, projecting, and forming a predominating feature, whilst the glossal tubercles are unusually developed, becoming in some even long bony growths.

The second variety of skull is smaller, of mesaticephalic form, and of neat outline, but it presents a prominent prognathous upper jaw, which gives it a very peculiar and distinctive appearance. The nose is short, wide, and often turned up, with depressed bridge. The lower jaw is softer in outline, less massive, rounded, and does not possess the harsh shape and strong markings of the Scandinavian type; the chin is little, if at all, prominent, and the appearance of the face is such as we have numerous examples of still in the south and west of Ireland, especially in inland districts, where the Celt has remained free from intermixture with Danish blood. I believe this form of skull represents a race that inhabited this country from a much earlier date than our Danish colonists.

No such discovery of the remains of races inhabiting Ireland about the 10th or 11th century has been as yet unearthed, and all the circumstances point to about this period as being the time in which they were buried; they, therefore, possess special ethnological interest. They cannot be the remains of persons slain in battle, for young and old, infants and women, idiots and cripples, were alike victims of the slaughter, and that they were also stripped and plundered is shown by the almost total absence of objects of personal ornament or even dress in any form. History, so far as we can ascertain, affords us no record of this exact transaction, but Irish and English annals tell us of similar destructive raids made along all the seaboards of the British Isles from the 8th to the 11th century, by bands of plundering Black Danes or pirates, and whilst we possess tolerably accurate records of such events as then took place in the north and south of this island during these troublous times, unfortunately, all traces of the local events that occurred in the province of Leinster, and especially about Dublin, appear to have perished altogether.

*Additional Notes.*—Since writing the above account I have read over the paper which was published by the late Sir William Wilde, and laid before the King and Queen's College of Physicians in the year 1844, upon the "Ethnology of the Ancient Irish Races." Sir William regarded the question from a considerably earlier period in our history, for his observations relate almost without exception to those forms of crania which are obtained from barrows, tumuli, and kistvaens, all primitive varieties of interment employed by races in Ireland in distant ages, far antecedent to the date at which the Donnybrook mound was formed. The conclusions at which he arrived may be compared, with much interest, along with those that appear justified by our examinations of the Donnybrook remains. Thus he has directed special notice to two different varieties of crania, both belonging to, and distinctive of, our early Irish races, whilst he further figured and described as referable to a much later period in time, the crania of Danish and Scandinavian origin, the latter being similar to those which I have obtained possessing Danish characteristics.

Now of the two primitive Irish races which he designates as Firbolg and Celt, he has given typical figures. One of these, the Firbolg cranium, will, in all probability, correspond with the remarkable dolichocephalic skull that I have described. These "long-headed, black-visaged, dark-haired, swarthy aborigines," possessed skulls that are principally characterised by "their extreme length from before backwards, or what is technically termed the "antero-posterior diameter and the flatness of their sides." He says in addition, "Now we find similar conditions of head still existing among the modern inhabitants of this country, particularly beyond the Shannon, where the darker Firbolg race may still be traced as distinct from the more globular-headed, light-eyed, fair-haired Celtic people who live to the north-east of that river."

The earlier primitive interments of the Celtic race are to be found in kintvaens or sandstone chambers, and probably they were the race that used urn-burial also. Their origin, whence they came, and what countries they inhabited before arriving here, has proved a fertile field for speculation, but still remains an unsettled question. They may be, and probably are, the race termed in old Irish annals the "Tuatha de Danaan," who are said to have invaded and overcome the original Firbolg inhabitants, and they would seem to have introdnced, or at least known the use of, bronze weapons, just as at a much later period, and within historic times, the Scandinavian races were distinguished for their knowledge and free use of weapons made of iron. The crania of these Celts are "better proportioned, higher, more globular, and approach more to the better forms of Indo-European, or Caucasian skulls.

We notice, therefore, in Sir William Wildes' memoir, three separate and distinct classes of skull found in Ireland, the Firbolg, Celtic, and Dane, and it was with much surprise and interest that, after collecting all the crania I could secure from the Donnybrook mound, and submitting them to rigid examination and the most accurate of all modes of testing, namely, careful measurement and calculation, that from the group three different varieties of crania were evolved. One of these—the rarest of all—was a long-headed form of skull of low organisation, that fairly corresponds with that of a Firbolg. Much more numerous were the class of Celtic skulls, properly so-called; and in addition we had types different from both, and ranging themselves with those of Scandinavian origin, and with British skulls derived from Scandinavian ancestry.

I wish to add further, that being convinced from the different osteological peculiarities of the human remains that were obtained in this mound, that further careful research would yield the "humeri with perforation of the olecranon cavity," a characteristic feature of less importance than the discovery of platycnemic tibæ, but still one of much interest and value for corroboration of the primitive period to which these bones must be referred, as it is a condition of bony structure which dates back as an ordinary racial character to the Polished Stone Period, and to that of the Dolmen builders, and might reasonably be expected to be found in conjunction with the platycnemic tibiæ, that I directed the workmen to make special search for these perforated humeri, and they have been accordingly found as I expected they would be, thus affording an additional point of much interest in the history of the discovery and one worth recording.

◆

## THE HABITUAL DRUNKARDS ACT OF 1879: HOW IT MAY BE ADMINISTERED, WITH AN ACCOUNT OF A RECENT VISIT TO THE AMERICAN INEBRIATE HOMES. (*a*)

By STEPHEN SHUTE ALFORD, F.R.C.S. Eng.

The Habitual Drunkards Act of 1879 is the result of the agitation of a small but influential society, organised on September 22, 1876, when Dr. Alfred Carpenter, of Croydon, presided at a meeting held at the Charing Cross Hotel, and called the "Society for Promoting Legislation for the Control and Cure of Habitual Drunkards." Lord Shaftesbury became the president, Dr. Carpenter the treasurer, and the author of this paper the honorary secretary. To the unwearied exertions of this society the much needed, and at legnth achieved, legislation is mainly due.

The public had long been perplexed by the helpless condition of habitual drunkards, the insane infatuation of their drink-craving, and the consequent abandonment, which tended undoubtedly to the fostering of crime, lunacy, and pauperism; and hence the conviction was entertained that, unaided, they were powerless to extricate themselves.

Mr. Alford showed that the public had long been perplexed by the helpless condition of habitual drunkards. In 1839 Dr. R. B. Grindrod, of Great Malvern, in his prize essay, "Bacchus," showed the great importance of restraining this helpless class, which he held would be an act of mercy. In 1855 and 1857 the Scottish Lunacy Commissioners reported on this question. Dr. A. Peddie, of Edinburgh, from 1858 to the present time, had been continually urging the necessity for legislation for the control and treatment of insane drinkers, and Sir Robert Christison, of Edinburgh, had often brought the subject forward in lectures and addresses.

These had been the pioneers of the movement. An important deputation to Mr. Cross, the Home Secretary, was organised in 1875, and had had a special committee on the question since that time. The more general Society, which was instrumental in framing the Bill and securing Dr. Cameron to take charge of it, was an outcome from this committee. Dr. Forbes Winslow published a pamphlet on "Uncontrollable Drunkenness" in 1866, and Mr. Turner, a solicitor, in 1867, prepared a short Bill as an amendment of the law of lunacy, to include habitual drunkards. In 1868 Colonel Akroyd, with the assistance of the Licensing System Amendment Association, also took up the question, and assisted the late Dr. Dalrymple, M.P. for Bath, who in 1872 obtained a Committee of the House of Commons to inquire into the subject, and framed a Bill on the report of the Committee; but his premature death stopped further progress.

The class intended to be benefited are persons of a susceptible nervous temperament, easily overcome by stimulants, whose nerve-power is soon used up—who, working under pressure, become exhausted, and acquire an irresistible drink-craving, from which, unaided, they cannot extricate themselves. Gross, vicious drinkers are not the class that could often be permanently benefited by this Act. The Act is tentative, only remaining in force ten years, and is in no way compulsory. None can come under its provisions except by their own voluntary act, declared and attested before two justices of the peace. No one can be detained more than twelve months in an inebriate retreat, but during the time of their detention they must submit to the rules of the house. Provision is made for registration and regular inspection, and all retreats are to be specially licensed.

Mr. Alford then gave a detailed account of his recent visit to five inebriate homes in the United States and one in Canada. There are twenty-six inebriate homes in the United States, and charters have been obtained for fourteen more. Most of the local Governments in Canada and the United States have laws recognising and authorising the control of inebriates. The chief obstacle to a more general establishment of these homes, he found, arose from the want of a recognised uniform plan of management. The one inebriate home in Canada is near Quebec, and associated with a lunatic asylum, which hindered its success, but much good had resulted.

At Chicago the author resided for three days in an inebriate home containing 77 patients, with whom he associated and conversed. Many had been sent into the home having no hope or intention of recovery, but from the kind influence exerted had been restored to society. Mr. Alford saw several who had been sent in by justices, who had been

---

(*a*) Abstract of a paper read before the Social Science Association, Monday, February 2nd, 1880.

restored for several years, and were most grateful, having full confidence in their permanent recovery, and power to abstain for the future from stimulants.

At St. Louis a sanatorium has been very successful, especially with opium cases, which (the reader found) abounded in America.

At Philadelphia, in the Franklin Home, there were 37 inebriates; much good work had also been done by this Institution.

The author stayed a few days with Dr. Parrish, of Burlington, New Jersey, who had devoted his life to this cause, and who gave evidence in 1872 before the Committee of the House of Commons.

At the Fort Hamilton Inebriate Home, Brooklyn, New York, he resided 11 days. There were 116 patients—90 sent by justices and 26 voluntary patients. This home is subsidised with 15 per cent. on saloon licenses by the State of New York, and receives all hopeful cases committed for drunkenness and crimes which are the immediate result of drunkenness. The Rev. J. Willitt, the superintendent, had had great success, especially in rescuing cases of *mania a potu* from permanent insanity; he considered 45 such cases were saved at that home in 1878. The patients sent in by law do nearly all the work of the institution and grounds, of which there are 26 acres attached to the house. Voluntary patients pay; about £3,000 was received from them in 1879. Fully 35 per cent. of the patients recover and return to society.

The Washingtonian Home, Boston, the oldest in America, had been in operation 22 years, chiefly under Dr. Day, its founder. The author stayed here two days. The plan adopted was chiefly moral, little or no restraint being exercised. Fair success resulted, but more frequent relapses than in other institutions where there is a stricter supervision.

In all the inebriate institutions religious influence was brought to bear, but attendance at the services was voluntary. Six months or more was found necessary for complete recuperation of the will-power.

Mr. Alford then gave examples of several inebriates who had been placed against their will in inebriate institutions; but from the kind and judicious treatment received, and the lengthened period of their forced detention, they had thoroughly recovered—one was then a leading preacher in Boston.

While Mr. Alford was at Fort Hamilton, a meeting was held of influential medical men and others to give him information on the subject. Various resolutions were passed, referring to the successful working of inebriate institutions under proper management. It was considered that there were at least 35 per cent. satisfactory recoveries from confirmed inebriety.

In conclusion, the author of the paper said that several institutions existed in Great Britain for the care and treatment of dipsomaniacs, but their usefulness had been limited by want of proper power of control. Two exist in the south of London, for females of the lower class, at Spelthorne Sanatorium, Feltham, and the St. James' Inebriate Home, Kennington. None exist for males. A society is being formed to establish a "Dalrymple Retreat for the Treatment of Inebriates," under the new Act, to be founded by contributions, but afterwards supported by the payment of patients. This will be at first for males, to meet the demand for such. He hoped the philanthropic public would come forward, and thus afford an opportunity for bringing the Act into operation. He considered £2,000 would be ample for starting such an institution.

◆

THE fogs in London last week were very destructive to human life; deaths from affections of the respiratory organs rose from 512 to 757. Of these, 531 resulted from bronchial affections, and 149 from pneumonia, besides many fatal accidents in the streets and on railways,

# Clinical Records.

## HOPITAL SAINT-LOUIS, PARIS.

### *Case of General Melano-derma with Lesion of the Supra-renal Capsule.*

Under the care of DR. HILLAIRIT.

THE account of this case was read by M. Gaucher before the Clinical Society of Paris, (*a*) and was that of a woman who died from an affection foreign to the skin trouble, and in whom the autopsy revealed a remarkable lesion of the supra-renal capsules.

The patient, a laundress, æt. 56, apparently of good constitution, and fairly stout, came under M. Hillairit's care at St. Louis, July 1, 1879, for erysipelas of the face, which was cured in a few days without presenting any peculiar features. She had, at the same time, on the left leg, irregular excavated ulcerations, manifestly syphilitic in their nature. There were, besides, on right leg and on the thighs, pigmented cicatrices of a blackish or coppery colour, whose appearance placed the specific origin of these lesions beyond a doubt.

As soon as the erysipelas was cured, the woman was put under iodide of potassium. She did not complain, appeared to have no suffering, her functions were regular, in fact she seemed going to complete recovery, when on the 16th July, during the visit at 10 a.m., her neighbour perceived that she had died suddenly in syncope. Vain attempts were made to revive her by revulsion and even by artificial respiration.

The autopsy was made 24 hours after death with the following results: There was about a glassful of lemon-coloured pus in each pleural cavity, and the same quantity in the pericardium; no adhesions of these membranes.

*Lungs.*—Slightly congested, but no trace of pulmonary embolism.

*Heart.*—Large and dilated, aortic valves sufficient, muscular substance of normal consistence and colour. There were no clots in the heart or larger vessels; the blood on the contrary liquid, diffluent, little changed in colour. There was slight atheroma of the endocardium on the aortic valves and below them. The aorta on the other hand showed advanced atheromatous lesions, at the arch and in the dorsal portion; its internal surface was dull, eroded, and had large calcareous patches. There was considerable dilatation of the vessel, the calibre of which was increased one-half at least. It is probably in this lesion that one must seek for the cause of death.

The arteries at the base of the brain were also slightly atheromatous, but there was no clot in the branches, either thrombic or embolic; not the least alteration of the cerebral substance, or cerebellum.

Except the supra-renal capsules, of which we shall speak presently, all the organs appeared in their normal condition; there was only one calcareous patch on the convex surface of the spleen, and a small supplementary spleen the size of a nut. No lesion of liver or kidneys. No varix of the lower limbs; no clots in the iliac or femoral veins.

These details are given in order that the death may not be attributed to embolism, and there remains no explanation for it but syncope.

*Supra-Renal Capsules.*—These bodies, the alterations in which constitute the interesting part of the case, were of normal size, but fluctuated to the touch. Each of them contained a single cystic central cavity, partly filled, not with liquid, but with a sort of yellowish caseous matter. Under the microscope this matter contained mostly fat, some cellular and nucleated bodies of an undetermined nature, and some granules.

It will be seen that these lesions resemble much those which have been found in a certain number of cases of

---

(*a*) *La France Médicale*, Jan. 7, 1880.

Addison's disease, and hence this case appears to me important. It is well, however, to remark that in this case there were no other symptoms than melano-derma, and some of the ordinary phenomena of the "bronzed-skin" disease. Can we conclude that there is a direct relation between a black colour of the skin and lesion of the suprarenal capsules? It is probable, and if these cases multiply we may be able to dissociate in some degree the complete elements of Addison's disease, and to prove that in that affection the melano-derma alone depends upon the suprarenal change; whilst the nervous and digestive troubles, the gradual weakening, and the other symptoms are allied more especially to lesions of the solar plexus and the sympathetic.

# Transactions of Societies.

## HARVEIAN SOCIETY.

FEB. 5th, 1880.

H. POWER, Esq., F.R.C.S., the President, in the chair.

### TALIPES VARUS IN AN ADULT.

MR. OSMAN VINCENT exhibited a female of 24 years of age, who recently had talipes, her parents having objected to any operation previously. A cast was shown of the foot before operation. She then walked upon a bursa with thickened skin. He first cut the tendons of the tibialis anticus and posticus, and 53 days afterwards the tendo Achilles, there having been much improvement in the meantime. An instrument was exhibited which had been used several hours daily to stretch the tendons and force the foot into its natural form, which is worked by the patient. The patient wore an ordinary boot, and the foot was quite straight, though considerably shorter than the other foot. It was rare now to find an adult case, as almost all are operated upon in infancy. There was no tendency for the foot to relapse in adults.

### KNOCK-KNEE.

Mr. VINCENT also showed a boy of 15, who was born in the country, and who was brought up to London at the age of 6; and who then began to develope knock-knee. He had been treated several times by long splints, but the treatment had never been continued long enough together for success. When first seen by him the ankles could not be brought nearer each other than nine inches. He was first put into a "trough-splint," when he progressed swiftly and steadily; after which he was put into upright splints up to the hips. He can now hold a penny betwixt his ankles with his instruments off. Operative procedures upon the bones in these cases, in his opinion, is unwarrantable when the above results can be attained otherwise.

The PRESIDENT and Mr. WALTER PYE spoke, after which Mr. VINCENT replied.

### NERVE STRETCHING.

Mr. WALTER PYE then read the paper of the evening on nerve stretching. A patient had suffered for many years with severe sciatica, for the treatment of which huge doses of morphia had been used. The patient was in severe pain when not under the influence of morphia. The nerve having been laid bare, it was pulled backwards and forwards forcibly with from eight to ten pounds pressure. The wound healed well, the pain was lost, and some paresis followed. The paresis wore off, and some pain was felt in the lower leg, but there was no return of the sciatica. The patient was able to resume work. The sciatica was probably rheumatic. The list of cases of nerve-stretching yet performed is not large enough to settle the question of the justifiableness of the operation. Mr. Pye then reviewed very carefully the history of the operation. It has been less successful in the treatment of tetanus than neuralgia. When the nerve was compressed by an inflammatory area the operation promised well. In cases where the skin had become altered a change towards the normal condition followed as well as the relief of pain.

The PRESIDENT and Dr. VEREKER BINDON spoke, after which Mr. PYE replied, and the meeting then adjourned.

## EPIDEMIOLOGICAL SOCIETY.

Sir JOSEPH FAYRER, K.C.S.I., M.D., F.R.S., President.

AT a meeting of this Society, held in University College, Gower Street, on Wednesday, Feb. 4th, Deputy Surgeon-General EWART, M.D., read a paper on

### ENTERIC FEVER IN INDIA, WITH SOME OBSERVATIONS ON ITS PROBABLE ETIOLOGY IN THAT COUNTRY,

of which the following is an abstract:—

That enteric fever has long found a congenial home in our Eastern empire may be gleaned from the classical works of Clarke, Annesley, and Twining, but the honour of first identifying it there on the perfected lines laid down by Gerhard, Stewart, and Jenner, belongs exclusively to Surgeon-Major Scriven, of the Bengal Medical Service, who proved the existence of this disease by a post-mortem examination of a case at Meerut, in November, 1851, and who subsequently published notes of cases met with in Burmah and Calcutta. The subjects of the disease were young Europeans. In the latter part of 1855 Dr. Ewart detected enteric fever among the native prisoners in the Ajmeer jail, Rajputana, and published in the seventh number of the "Indian Annals" an epitome of the symptoms and post-mortem appearances found in these cases. In this paper he stated that without scrutinising post-mortem examinations in fatal cases of so-called remittent fever the diagnosis must be doubtful, and he suggested that many of these might be examples of typhoid and typhus fever. Dr. Ewart subsequently recorded well-marked cases of enteric fever occurring in a native regiment in Kherwarrah, Rajputana, and the aborigines of the district, especially in the autumn and early months of the cold or winter season, when the worst forms of malarious remittents abound. In 1860 he noticed the prevalence of relapsing fever, and that many of the so-called malarious remittents were simply typhoid or typhus fever marked by malarious poisoning. Frequently the patient succumbs to the combined influence of the enteric and malarial poisons at an early period of his illness. In three of his patients in Calcutta who died after being ill from eight to twelve days, there was very marked prominence of the agminated glands. Had these patients survived long enough the glands would have ulcerated. In both natives and Europeans who have suffered from malaria the morning remission of temperature is more marked during their attack from enteric fever. In natives the rash is present, but is less obvious than in Europeans. There is no intimate relationship between the alleged potential cause of genuine paroxysmal fevers and the poison of enteric fever. Nor is it necessary to accept in its entirety the pythogenic theory of the origin of the latter disease, yet the intensely insanitary condition of the cities, towns, and villages throughout India renders it inexpedient to dispense with the pythogenic theory as unquestionably the best working hypothesis hitherto advanced to explain the endemic prevalence of the disease in that country. Whether or not the poison can be generated in such a nidus *de novo*, it is in some way or other intimately associated with the presence of animal matter or filth undergoing putrefactive metamorphosis. When he detected enteric fever among the native prisoners of the Ajmeer jail, no word-painting could exaggerate the abominable filthiness of the sleeping accommodation set apart for convicts. A few earthenware vessels were provided as urinals and commodes. The filth was taken away, but much of it was washed into narrow channels leading to a cesspool adjoining the wall from which drinking water was drawn. In Calcutta enteric fever was most abundant in the autumn, and the modifying power of malaria most apparent in the autumn and first half of the cold season, becoming less so in the middle and end and scarcely perceptible in the remainder of the winter and during the hot months. Strangers of the dark and fair races were most exposed to attack. The same insanitary conditions considered to be at the foundation of the disease in temperate regions, exist to a very marked extent in Calcutta. Until the last few years filthy open drains lined the streets of the European quarter as these did down to 1876, and do now in most parts of the native town. The sewers also are faulty in construction, being porous, and not lined with any impervious material. The sanitary defects of the native town exist in an exaggerated degree, the water supply being in many instances very impure. The reports of the sanitary commissioners throughout India show that similar insanitary conditions are common throughout the whole country; but we are met with the assertion that such conditions do not exist in military hospitals, barracks, and stations. They are to be found, however, in unmitigated intensity in bazaars frequented by the soldiery. The sanitary perfection of these parts is, therefore, outside the question. There is no reason to deny that enteric fever in India is due to the same source or causes which in some way or other are considered potential in its production in this or temperate climates. In short, there is nothing repugnant to the Murchisonian doctrine that in its etiology it is intimately associated with the presence of animal or fæcal filth. The fever would be still more frequent in India than it is if the superabundant filth everywhere met with were not exposed daily to the powerful antiseptic influences of the atmosphere and the sunlight. In the Madras Command there has been difficulty in tracing the disease to pythogenic causes, notwithstanding the fact that the military stations are surrounded with filthy bazaars. In this investigation there is no evidence to show that the incubating period of the disease had been sufficiently considered. Until this has been done it is premature to look for other than pythogenic causes. The opposition to the received opinions regarding the causation of enteric fever will do no harm, because, as we already know, it has stimulated research and clinical observation. This is already evident from the fact that in the last report of the Surgeon-General several well-marked cases of the disease are recorded in great detail. In conclusion, Dr. Ewart protested against the present system of deodorising the evacuation of enteric and cholera cases simply by the use of dry earth. Carbolic acid, chloride of zinc, or sulphate of iron solutions should be employed. If not available they should be burnt.

In the discussion which followed the reading of the paper, Sir Joseph Fayrer, Surgeon-General Murray, Surgeon-General Gordon, Surgeon-General Francis, Dr. Norman Chevers, Surgeon-Major Don, Mr. Smee, and Dr. Theodore Duka took part.

◆

## SURGICAL SOCIETY OF IRELAND.

### SESSION OF 1879-80.

A MEETING of the Surgical Society of Ireland was held in the Albert Hall, Royal College of Surgeons, on Friday evening, January 16, 1880. Dr. MAPOTHER, President of the College, occupied the chair.

Mr. B. WILLS RICHARDSON, Hon. Sec., read the minutes of the previous meeting, which were signed.

### VESICAL CALCULUS.

Mr. B. WILLS RICHARDSON exhibited a specimen of calculus which he removed from the bladder of a boy, æt. 4, a few weeks ago in the Adelaide Hospital, and which was remarkable for its shape, its longest diameter being 1 in. 6-8ths, and its shortest 6-8ths of an inch only. It seemed to have formed a bar across the bladder, both ends being thickly capped with triple phosphates, the middle portion being scarcely at all coated with them. Mr. Abraham, the College Curator, had kindly made a section of, and analysed, the calculus. He states that it is composed chiefly of uric acid deposited in concentric laminæ, the incrustration being triple phosphates. Owing to its great relative length he (Mr. Richardson) thought it might contain a nucleus formed by some foreign body, straw or a bit of stick, for example; but there was nothing of the kind, the nucleus being also formed of lithic acid.

### CARIES.

Mr. WHEELER exhibited the right arm of a lady, æt. 68, which he amputated last Tuesday, for caries. About two years ago she was seized with pain in her arm and elbow-joint, for which she was treated homœopathically. She does not appear to have permanently benefited by that treatment, for an opening formed near the external condyle. On passing a probe the real nature and extent of the disease were obvious. I explained to the patient that amputation would be necessary. This was also the opinion of Mr. Butcher. I promised, however, first to try removal of bone only. To the affection as it appears here some apply the term atonic caries. The points in the specimen are most important to be observed in order to form a correct diagnosis. The opening in the skin is thin and undermined; the edges are sharp, not fungating; there was a serous discharge, commonly called "ichorous pus," not that stringy, pus-like synovia; the cellular tissue and the skin are œdematous, and where I made the examination with the probe I came at once on roughened bone. All these points indicated atonic caries, not exuberant or fungating caries, and therefore less hopeful for conservative measures. Not a vestige almost of the large synovial membrane is to be seen, save where it lines the olecranon depression. The lateral and anterior ligaments are intact. The orbicular ligament is partially destroyed close to where the synovial ligament pouches towards the lesser sigmoid cavity. The olecranon is denuded on its articular aspect, and its posterior surface is rough and worm-eaten. The ulna is diseased for about half-an-inch. The head of the radius has lost its cartilaginous covering, and is carious on its inner side. This portion of bone was lying loose, separated from the outer and anterior part of the much diseased inner condyle. The external condyle is partially separated, roughened, and worm-eaten in appearance, as also the shaft of the humerus for about four inches up.

Professor BENNETT read a communication on

### ACUTE MENSTRUAL GOITRE AND ITS TREATMENT BY TRACHEOTOMY.

which will be found upon page 101.

The PRESIDENT said he was sure anyone who had heard the paper read, or who would hereafter read it, could not fail to feel intense interest in it as dealing with a very original subject, and showing the prompt operative skill with which one of the cases was met. He asked Mr. Bennett if, in reading up the literature of the case, he had found that the disease was confined exclusively to females, and connected with the menstrual functions.

Mr. ED. HAMILTON inquired what was the cause of death in the second case, in which it seemed to have occurred with great rapidity, and could scarcely be accounted for by anything like congestion in the thyroid body. It seemed to him that death had occurred through spasm affecting the muscles. Dr. Henry Kennedy had reminded him of a proceeding by which in such cases a free division of the fascia covering the enlarged thyroid body might be attended with some relief, independent of the operation of tracheotomy. Of course that proceeding would be attended with the danger of hæmorrhage if the deeper structures were wounded. However, he had some recollection of a case in Steevens' Hospital in which the operation was attended with great relief. The patient, who was under the care of the late Mr. Samuel Cusack, was suffering from intense dyspnœa, and the division of the fascia over the gland gave considerable relief. There was another mode of practice also that might afford relief, namely, the application of leeches in large numbers to the gland. Dr. Bennett's paper was of great interest, dealing as it did with a subject that was to a great extent new.

Mr. STOKES asked if there was any special reason why operative interference was not had recourse to in the second case? In reference to the operative procedure in the first case, the patient was still wearing, and likely to continue to wear, a tube in the trachea, and he suggested whether the old practice, now obsolete, of cutting a circular piece out of the trachea and establishing an aërial fistula might not obviate the necessity of wearing an artificial tube in the wind-pipe. He was not aware there had been any similar cases, in Dublin at all events, put on record, and therefore the value of the communication was very much enhanced.

Dr. WM. FRASER said the only case of tracheotomy he ever saw for goitre occurred in the practice of the late Dr. Hutton in a lad, æt. 11. In that case the obstructing cause was considered to be a prolongation of the gland behind the trachea, and between it and the œsophagus. He was long in hospital, and was saved from suffocation by the operation.

Mr. HENRY GRAY CROLY referred to the case of a boy, æt. 14, who suffered from acute goitre, where the isthmus of the thyroid body passed between the œsophagus and the trachea, producing croupy breathing. The symptoms were relieved by the rapid introduction of iodine. He had seen cases where patients, the subject of goitre, were attacked with cellulitis of the neck, and where free incisions dividing the cervical fascia had relieved the symptoms.

Prof. BENNETT replied. He said the President's question was, he thought, answered by Dr. Fraser. In looking through the literature of the subject it was notorious through all authorities, both as to vascular and as to endemic, and also with reference to goitre development at the period of puberty, that the young male to a certain degree was just as liable to it as the young female. Mr. Hamilton had asked how the second girl died. She died, he had no hesitation in saying, of apnœa or asphyxia, indicated by the livid face and bloody froth in the mouth. He saw the dead body, and the lips were frothing just as if she had been strangled. No doubt the division of the fascia had been attended with success. The late Mr. Maurice Collis told him of a case of the kind at the Meath Hospital, where he operated, not so much for enlarged thyroid as laryngeal distress of an unexplained character, supposed to be hysterical. Sir Philip Crampton was present, and said the case was a suitable one for tracheotomy. In reference to Mr. Hamilton's suggestion of leeching, the advisability of such a course of procedure was discussed in the second case, but not in the first, in which the necessity for prompt action was too great to wait for that method; and in the second, looking on the disease as rather anæmic, to establish a complete menstrual flow they did not think leeching would tend in that direction. However, the experience of the two cases would incline him not to leech, but to bleed at the bend of the elbow, and see the result. That course did not occur to them in either of the cases. Mr. Stokes asked why operative interference was not undertaken in the second case. That was a question he could not answer, because he was not present; but he had no doubt if operative interference had been undertaken it might be attended with success. However, no operative interference was attempted, the surgeon present not being willing to undertake it. As to establishing an aerial fistula in the trachea, he was quite satisfied it was not the tracheal opening in which a tube had been worn that contracted, but the skin and superficial parts contracted, so as to close the wound, and he would not trust for any length of time to a fistula in an individual in the condition of the girl in question; he would far prefer to leave in the silver tube. Mr. Croly had alluded to a group of cases where the isthmus of the thyroid body passed between the œsophagus and the trachea, or even behind both; but such cases were exceptional in their nature, and due to the position of the body rather than to sudden disturbance, so that they were not cases in point to consider at present.

# Department of Lunacy.

## DR. BUCKNILL ON PRIVATE LUNATIC ASYLUMS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to thank you most sincerely for your able leader in defence of an honourable body of gentlemen, whose reputations have been so foully aspersed by Dr. Bucknill. At the same time, I shall be glad if you can accord me space in your valuable columns for a few words on a matter which is of such vital importance to the profession and the community at large. I was present at the adjourned meeting of the Metropolitan Counties' Branch of the British Medical Association on Wednesday last, when I made the following remarks in reply to Dr. Bucknill's attack of the previous meeting. I said:—

"There are few subjects that can engage the serious attention and consideration of the friend of humanity of more importance, and, at the same time, of more painful interest, than the condition of the insane. Degraded below his species, and reduced to the level of the beast which perishes, the hapless lunatic wanders, frail, helpless, uncared-for, on the shores of this great universe, depending for very existence upon the sympathy of those more fortunate. But, alas! too often those under whose supervision he has been placed, instead of being assisted and aided in their sacred mission to bring him back to light and reason by kindness and protection, are harassed and interfered with in their work by unjust accusations and groundless assertions on the part of some persons who are strongly prejudiced.

"I approach a consideration of the subject in no unfriendly spirit with the gentleman who opened the debate on the last occasion. Dr. Bucknill is one for whose opinion I have always entertained the greatest respect and esteem, and from his world-wide reputation and skill, it is with a certain amount of apprehension and diffidence that I find myself, as I do on this occasion, diametrically opposed to his views. I trust that any remarks I may make this evening may be accepted *cum pleno animo*, and in no other way. The question of the abolition of private asylums is one which, from time to time, has cropped up generally as a rule after some sensational case of lunacy which has occupied the attention of our law courts, and has been made a *bête noir* for attacking these institutions and their proprietors. It is an extraordinary fact, however, that in all the recent great lunacy trials private asylums have come out of the attack without a single impeachment against them, whilst their proprietors remain unspotted and unscathed. Notwithstanding this, the cry is still for their abolition. For many years committees of the Houses of Parliament have sat at various intervals to discuss private asylums and their management. Mainly through the exertions of Lord Shaftesbury, we have our present Act, 8 and 9 Vic., cap. 100, sec. 96, and which many attempts have been made to upset. I think, however, I must draw your attention to the late Committee of the House, which sat two years back. After various allegations and accusations had been brought against proprietors of private asylums, and the evidence had been heard *pro* and *con.* the following appears in the Report of the Lunacy Committee as the result of their investigations—that no *mala fides* has been proved against the medical proprietors of private asylums. After this the matter should have ended, at least, for the present. It has, however, been again brought forward with renewed vigour and renewed opposition. In the year 1859 Lord Shaftesbury gave evidence before the then sitting Lunacy Committee, which was condemnatory of private asylums, but at the recent investigation by the Lunacy Committee he said, in reply to a question as to the present state of private asylums—'At present, from a variety of causes, the licensed houses are in a far better condition in every sense of the word. More is expended on them by the proprietors, and I must do them the justice to say that the change is very great, and, so far as the evidence I gave in 1859 is correct, I should not give it now. I can speak in high terms of many licensed houses and their proprietors, but I will add that if you relax your vigilance ever so litte, whether it be of licensed houses or of hospitals, or of county asylums, the whole thing will speedily go back to its former level.' These are the words and the opinion of one for whom we have the greatest respect, as he speaks authoritatively on the question.

I am not here this evening to defend our Act of Parliament, but to endeavour to show that we perform our duties in a right spirit. Is it just that the proprietors of private asylums should be held up to opprobrium? Individually speaking, which may also be taken as the opinion of those physicians and surgeons who are the licensed proprietors of private asylums, I say that when it can be proved that we have detained patients in our asylums longer than is absolutely necessary for their welfare and cure, or have received them when we ought not to have done so, so soon I say erase our names from your medical associations, strike us out from being members of our medical corporations, deprive us of those diplomas which we have so honourably obtained, and of those degrees which we have earned—banish us, I say, from society, and leave us to grovel about the earth as a disgrace to humanity; therefore, anyone who so insults medical proprietors of private asylums, insults the whole of the profession. For have we not studied at the same medical schools? Do we not hold the same degrees? Have we not had the same medical teaching, the same moral and social training as you? Have we not all the same feelings and desire to act honourably? The poor unhappy persons are not now chained like felons to some foul pestilential dungeon, there left to the gaze of those anxious to gratify a morbid curiosity. Gratitude and immortal glory must be given to those who exposed and laid bare these frightful atrocities, and so assisted the physician "in ministering to a mind diseased," and those names will stand prominently and most honourably forward in the history of civilisation. Philanthropy was never more needed or employed to better purpose.

I have no wish or desire to attempt to suggest legislative measures for private asylums; suffice it to say that I shall hail with pleasure my clause in the new Act, which shall be of itself sufficient to protect proprietors from a possibility of accusation. I have simply come here stung to indignation with the unjust stigma, and to maintain and protect what is dearer to an Englishman than his life, his honour—this I have come to-night to vindicate.

"He who steals my purse steals trash,
But he who filches from me my good name,
Robs me of that which not enriches him,
And makes me poor indeed."

I am, &c.,
L. S. Forbes Winslow, D.C.L. Oxon.

---

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As a superintendent of a Private Asylum, I cannot refrain from offering you my best thanks, and at the same time expressing my entire concurrence with the article in the *Medical Press and Circular*, January 28th, animadverting upon the statements made by Dr. Bucknill in a paper read at a recent meeting.

The sweeping assertions made against us as a class, by Dr. Bucknill, I think compel all medical superintendents to indignantly repudiate the scurrilous accusations against their honour and integrity.

Enough has been written and said explanatory of the improved means adopted in the present day, for the care and treatment of the mentally afflicted, both by those interested as I am, and by Government officials, to satisfy most ordinary mortals, and convince them of the groundless nature of this attack. The remarks Dr. Bucknill made with respect to our pecuniary motives in keeping private asylums, were most ill-advised and defamatory. What has been the motive of his medical career? Has it been pecuniary gain and celebrity, or simple philanthropy? One feels tempted to ask on what he lived—on "humanity," just as likely as on air. We cannot live on "humanity" without some small concomitants, though I expect we possess that virtue nearly in the same degree as Dr. Bucknill professes to do. We might fairly have expected something more reasonable from a gentleman so long a member of our profession. The old adage, "*Ingenuas dedicissi fideliterertes emollit mores nec sinit esse feros,*" seems to have signally failed in this case. Has he in the course of that period been guilty of such enormities, that he now repentantly judges others by himself?

I am fully aware that in his time the regulations were not so stringent as at present, and that laxity of management in different asylums was often reported; but I can boldly assert that such would not now be practicable, and further that the reports now issued are almost universally favourable.

In conclusion, I may say that I quite agree with Dr. Bucknill that asylums should be acquired by the State. I am perfectly willing to part with my own, though it has been in the possession of the family for many years, but I cannot tamely submit to the insulting arguments he adduces to gain that point.

I am sure that no one member of the general public who understood the amount of anxiety and work arising from the duties of a superintendent would begrudge him his remuneration, much less insinuate, as Dr. Bucknill does, that it was gained disreputably.

I remain, yours, &c.,
Superintendent.

◆

At the fortnightly meeting of the Metropolitan Asylums Board, on Saturday last, an outbreak of fever was reported on board the training ship *Shaftesbury*. Four boys had been removed to the Homerton Fever Hospital, where one had since died, and steps were at once taken to limit the outbreak to the cases which had already occurred.

---

Three coroners' inquests were held in London on Saturday, on the bodies of cabmen who had died from lengthened exposure to the fearful fogs of last week. The number of deaths from this cause, and from accidents occasioned thereby, will probably never be accurately ascertained; but their persistence for a whole fortnight is almost without a parallel, and the increase in the death-rate in consequence exceedingly great.

Registered for Transmission Abroad.

## DOES THE GENERAL MEDICAL COUNCIL REPRESENT THE MEDICAL PROFESSION?—III.

### THE INDIRECTLY CHOSEN REPRESENTATIVE OF THE LICENSING BODY.

Passing from our criticism upon the Crown nominees, upon the representatives of self-elective cliques, and upon those members who are chosen by executive Councils who are themselves elected by the fellows or medical graduates of licensing bodies, we complete our analysis by reference to the two remaining classes of members of the Medical Council.

The first of these divisions includes the members who are chosen by a mixed constituency of whom but a small proportion are medical men, the vast majority of the voters for a representative being persons who have neither knowledge of the functions nor much interest in the policy of him whom they select.

It will be observed that in these three Universities the representative is elected not by a family party as in Class 1, to which we have already referred, nor by a conclave nominated by the Crown, as in Class 2, nor by an elected council, as in Class 3, but by the direct vote of the entire constituency of graduates, medical and non-medical. Thus the gentlemen returned for these three Universities may certainly claim to speak the mind of the bodies for which they act, and to hold their seats by a constitutional tenure of office.

The following table makes this manifest:—

*Licensing Bodies whose Representative is Elected by a large number of Members.*

| Name. | By whom representative elected. | Number of Electors. | Number of Medical Electors. | By whom Electors Appointed. |
|---|---|---|---|---|
| Oxford University | Convocation | 5,026 | Say 100 | Elected by graduation |
| Cambridge University | The Senate | Nominally 5,500 actually about 250 | Say 100 | Elected by graduation |
| Durham University | Convocation | 280 | Say 25 | Elected by graduation |

But then the mind of the University in such a case is not a medical mind, and it will be plain from the foregoing table that these representatives are not in any fair sense the mouth-pieces of the profession. They are the chosen of nearly 11,000 University graduates, of whom, however, only about 225 are medical men. In other words, these gentlemen are the nominees of, say, 40 clergymen, barristers, and men of property for each medical man, and they therefore cannot be supposed to be even remotely influenced by the votes of the medical portion of their constituencies.

If, indeed, we need an illustration of the open contempt with which the opinions of the profession are treated by certain members of the General Medical Council, we will find that illustration in the person of Dr. Acland, who represented for twenty years the University which stands first on the foregoing list. Dr. Acland has been placed in the Presidential chair of the Council, although he has been at pains to express his entire disregard of the opinions of the profession on all material matters. He has treated with contumely the united remonstrances of English medical men as to his annihilation of the Oxford medical school. He has publicly displayed his carelessness for the opinions of his professional brethren, by his evidence before the Select Committee, and he has by his recently-printed answers to the recommendations of General Medical Council audaciously set at nought the requirements of the body over which he presides. We conclude that if the voice of the medical profession were as strong in the Medical Council and in the elective constituencies as it ought to be, and as it may be supposed by the public to be, Dr. Acland would not dare to treat our feelings and interests in such a way, and we are fully entitled to argue that he and others do so because they feel themselves wholly independent of the doctors and because they speak within a tribunal which itself has no regard for medical opinion.

The constituencies of these five bodies possess to the fullest extent their power over the acts of their representative, and their delegates may claim to be the embodiment of their opinions, interests, and feelings. The representatives of these five bodies are indeed the only delegates out of the whole Council of twenty-four which represent truly the opinions of the voters, in whose behalf they speak.

The last class of the Medical Council to whom we have refer to include the only five members who have any real claim to represent medical opinion. They are as follows:—

*Licensing Bodies whose Representative is Elected by Members of the Body.*

| Name. | By whom Representative elected. | Number of Electors | Number of Medical Electors | By whom Electors appointed. |
|---|---|---|---|---|
| College of Physicians, London .. .. | The Commonalty under Charter of Henry VIII., and Act 14 and 15 Henry VIII., cap. 5 | 307 | 307 | Themselves. |
| College of Surgeons of Edinburgh.. | The Fellows .. | 399 | .. | Themselves, partly by ballot, partly by examination. |
| College of Physicians of Edinburgh.. | The Fellows of the College who are on the roll .. | 73 | 73 | Themselves. |
| The Faculty of Glasgow | The Fellows .. | 170 | 170 | Themselves. |
| College of Physicians in Ireland .. | The Fellows .. | 52 | 52 | Themselves by ballot. |

We must point out, however, that, even in some of these bodies, the representative *locus standi* of the member is not very exalted. We do not consider that those Councillors who are chosen by a conclave to which admission is obtained by a secret vote can boast of representing anything but a family party; and this objection to their representative status is intensified when the family party is a small one. For instance, the representative of the Irish College of Physicians is a nominee of ostensibly 52—actually about 35—voters, and within the sacred precincts of the Fellowship of that College, no one would have a chance of entering if he were known to entertain aggressive views of any sort. We mean no disrespect to the Fellows of that College, they are as all must be who elect themselves, for reasons of which personality is one. We therefore cite the fact simply to show that the Medical Council representative of that College, or of any college similarly placed, does not stand upon ground as firm as that which he would occupy if he were the chosen of those who could prove their claims to the highest qualification granted by his College. He is certainly the direct nominee of graduates who are justly entitled to nominate, and, *pro tanto*, is a true representative and subject to their control, but he cannot be supposed to reflect the views of the profession at large, as we hold that every member of the Council should do.

Having thus concluded our analysis of the constitution of the General Medical Council, we believe we may claim to have demonstrated—

(*a*) That that body is *not* a medical Parliament, whatever it may be.

(*b*) That it represents educational cliques and professional respectability, but certainly not the medical profession.

(*c*) That not much more than one-twentieth (1,384 out of 22,841) of the entire profession have any power whatever of expressing an opinion as to the fitness of individual members, and

(*d*) That that twentieth are, as a matter of fact, utterly overwhelmed by the votes of laymen who know little, and in most instances care as little for the needs and aspirations of medical men.

We shall next week point the moral of our criticism by a few words on direct representation, and on the indefeasible right of our profession to speak with authority in the tribunal which settles our affairs.

◆

## THE HABITUAL DRUNKARDS ACT OF 1879.

The Society to whose unceasing exertions must be chiefly attributed the provisional Act of Parliament which came into operation on the first day of the present year convened a meeting on Monday, the 2nd Feb., to consider the probable consequences of the Bill. Mr. Stephen S. Alford, F.R.C.S., contributed a paper detailing his experiences of the working of inebriate homes in America, an abstract of which paper is contained in our present issue. From it the assurance is derivable that a very considerable benefit has been effected in the way of reclaiming those patients who have availed themselves of the restraining influence exercised on them, during their voluntary stay in the asylums. The success shown to have been secured in America is a very encouraging indication of the good results which can be expected to come of a healthy and firm system of treatment in these cases; and in the light of the most generally accepted theory that dipsomania is most accurately described as a specific disease, there is a manifest reason in the legislation which would provide for the proper reception and curative treatment of such as are sufferers by it. The tendency of the discussion which followed Mr. Alford's address was to admit the truth of this, but at the same time, to deprecate the halting inefficiency of a measure which stops short of insisting on the compulsory incarceration of those who are evidently permitted to be at large only at the expense of public safety. Too little emphasis, we cannot but feel, was laid on the important truth that the confirmed drunkard is as much a dangerous unit at large as is the lunatic, against whom summary proceedings are at once instituted as soon as his condition is known to the authorities. In hearty sympathy with the unwillingness to advert too harshly to a distressing infliction, and anxious to deal as gently as may be with the delicate considerations which hedge round the question, we are compelled, both from the experiences of ourselves and of numerous other observers, to believe that habitual drunkenness is as deadly a disease of modern life as the most fatal of nervous affections; not directly so much as by the indirect effects it produces on the drunkard himself, and—a far more important consideration—the evil it transmits by heredity. The hereditary tendency to drunkenness cannot be doubtful in face of evidence such as was afforded by Mr. Saunders, who speaking to the motion before the meeting, called attention to a speech of Sir Henry James, reported in the *Times* of Jan. 27th. The occasion referred to was that of the trial at Exeter of a man for the murder of his wife. In defending the prisoner, Sir H. James said there was the clearest proof that the culprit had inherited the passion for drink, and that the commission of the crime was solely attributable to a diseased condition due to its indulgence. Such cases are not uncommon, and are eminently fitted to be dealt with under a compulsory law.

The weak points of the existing Bill are chiefly two. In the first case it can be productive of little general advantage, since it enacts that preliminary to being confined in a retreat, the patient must voluntarily publish his condition before two magistrates, and avow his desire to become subjected to restraint; after which he is bound for a period not exceeding twelvemonths to remain under the rules of the establishment he elects to be confined in. The class of people who are likely to be assisted by the new institutions are just those who will least willingly submit to the indignity an exposure of their want of self-regulating power must entail; and this fatal flaw in what might have been a highly useful measure will go far to make the attempt at legislation an abortive effort to produce a good result. That voluntary seclusion, without the legalisation of compulsory retention for a period, fails of success has already been proved in this country. An experiment in this direction was some few years ago made by Dr. L. S. Forbes Winslow, and, under the most perfect management, being given a fair trial, it resulted in nothing, save heavy loss to the proprietor of the institution. This should go to show the commercial absurdity of the sixth section of the Act, which prohibits the granting of a license to any person who is already licensed to keep a house for the reception of lunatics. The direct connection between insanity and habitual drunkenness should be manifest even to lay perceptions. It is difficult indeed to comprehend how the framers of the Bill could have permitted this clause to be finally included. It is, of course, possible that the ten years which the Act is to be in force, will be a sufficiently lengthy time to demonstrate the shortcomings which are already patent to the majority of the profession; but—and here is the second weak point in the Act—this time-limit will itself be productive of defeat to the whole scheme. It had surely been a better plan to leave the question of its terminability entirely open, for at any time an influential representation of its inefficiency, or a popular outcry against its working, would have secured an inquiry that would effectually expose and amend it. So long as the prohibitive restrictions that now beset alike intending patients, and homes and retreats continue, so long, that is, as the appearance of legislation embodied in the Act of 1879 remains the only basis for the erection of checks on crime incident to habitual drunkenness, so long one of the diseases most inimical to the progress of civilisation will flourish unabated in our midst. That 90 per cent. of American patients in retreats, are voluntary inmates, lends no support to the theory that even 1 per cent. of the better class English dipsomaniacs will publish their desperate condition in the hope of regaining health, which must always be associated with the knowledge of disgrace under such conditions. Common sense reasoning infers that if a dangerous lunatic may be secured, and isolated in the interests of public safety, then equally ought the no less dangerous moral infection of drunken contagion to be forcibly prevented from spreading an injurious influence about. And again, who, more than the experienced in the care of insane patients, is fitter to direct the treatment of cases which are admittedly akin to mania. The original conception of the Act was a sweeping measure, which, it might have been hoped, would do considerable good. But the puerile, faltering fulfilment of the idea, that now tantalises the wretched victim of intemperate habits with the suggestion of cure, while it effectually bars the way to improvement by the erection of ridiculous hindrances, deserves, as it is receiving, the indignant condemnation of the earnest reformer.

Endeavouring to make the best of an unsatisfactory measure, the "Society for promoting Legislation for the Control and Cure of Habitual Drunkards" has decided to open a retreat to which impecunious persons may be sent. Dr. Hardwicke, coroner for Central Middlesex, expressed the opinion that the aims of such a retreat would be assisted if magistrates would offer the option of retirement to it rather than to prison, when cases likely to be benefited thereby were before them in the police courts, and undoubtedly this is true. Much, however, will depend on the judicious selection of the cases at first, for the promoters of the "Dalrymple Home" must be duly mindful of the fact that its success will be taken as a critical test of the value of the Act in operation; and accordingly as they can show a good or an indifferent report the ultimate future of the movement for compulsory powers will be effected. Dr. Norman Kerr rightly declared that the movement is nothing more than a farce until it results in definitive and productive action; but we doubt his estimate that a *small* house even, at all commensurate with the requirements of the scheme, can be maintained ten years for £10,000. However, the appeal has gone forth, and we trust that it will be responded to in a manner that will enable the committee to do something. That this something, under the shadow of an Act that will regulate the conduct of the committee, will amount to much we are less sanguine. But we can at least hope and feel the best that can be done will be done to prove that a comprehensive and consistent measure is necessary, and will be beneficial.

◆

## THE SENATE OF THE NEW IRISH UNIVERSITY.

SEVERAL speculative lists of the Senate of the New Irish University have been published, but as it is understood that none of them are strictly accurate, we refrain from reprinting them. It is, however, of much importance to the profession in Ireland, that the governing body of the institution which is to supersede the Queen's University, and to compete with the University of Dublin, shall have a sufficient medical and surgical element within it. This is decidedly important, because the terms upon which medical and surgical qualifications are to be granted are not formulated, either in the Act of Parliament or the New Charter, but will be wholly at the discretion of the New Senate; and if that body should be inadequately informed as to the necessities of medico-chirurgical education and qualification in Ireland, the new order of things might raise up a system even more objectionable than that of the Queen's University.

Although, as we have said, the actual list of Senators has not been promulgated, it is known that several Fellows of the Irish College of Physicians have been asked to serve. If we are rightly informed, this offer has been made to Sir Robert Kane, Drs. Banks, Cruise, Lyons, and Hayden, and to Sir Dominic Corrigan.

We observe with astonishment and regret that the rumoured list does not contain the name of a single surgeon, an omission which we hope we may regard as an inadvertence, although it is at best an inadvertence which should not have occurred. The Irish College of Surgeons has always occupied a public rank second to none of its sister institutions, and it has done public service which cannot be forgotten or ignored. Moreover its right to express an opinion on such a subject has been fully recognised when the draft Charter of the Queen's University was submitted to the College by the then chief secretary, Sir Thomas Redington. We hope we may anticipate that the Irish Government will hasten to amend so obvious an error in the constitution of the New University, and wipe away the public slight which that error has put upon the Irish College of Surgeons. We understand that the Council of the College has formally protested. Undoubtedly that protest will receive the approval and sympathy of the profession throughout the kingdom, and we cannot doubt that it will be regarded by the Government as a fair and reasonable complaint.

◆

# Notes on Current Topics.

### Metropolitan Hospital Sunday Fund.

A MEETING of the Council of the Hospital Sunday Fund took place last week, at the Mansion House. The Lord Mayor (Sir Francis Truscott), on taking the chair for the first time, said that he felt great interest in the movement, and that if his time, energy, and assistance could be of any avail in the promotion of Hospital Sunday he should not grudge giving either to the cause. The secretary having read several letters of regret from members unable to be present, announced the receipt of a donation of £105 from the trustees of the late James Drew, Esq., Professor Marks rose and said, before passing to the business of the day he thought it a duty to move a vote of condolence to Sir Sydney Waterlow, to whom the fund was so largely indebted, in the severe loss he had just sustained by the death of Lady Waterlow. Sir Rutherford Alcock, in a few well chosen words, supported the vote, and it was accordingly carried *nem. con.* The vacancies occasioned by deaths in the Council and the Distribution Committee were then filled up by the election of A. Willett, Esq., as the successor of the late Mr. Callender, whose loss was much to be deplored; the Bishop of Bedford was elected to fill the vacancy occasioned by the death of the Bishop of Guildford, and the Rev. Canon Moore that of Canon Oakeley. Sir Edmund Currie and Mr. Martin having consented to continue to act as hon. secretaries, Lord Stanhope proposed the re-election of the secretary, Mr. Custance, and in doing so, took occasion to speak of his services to the Fund in the highest terms of praise, and as a gentleman always most anxious to perform the onerous and arduous duties of his office to the satisfaction of all with whom he was brought in contact. It was left with the Lord Mayor to arrange a conference with the committee of management of the Hospital for Incurables, in accordance with a resolution passed at the annual meeting, and the proceedings were brought to a close with a vote of thanks to the Lord Mayor.

### Licensed Poisoning.

The Government label affixed to patent medicines is in more than one instance a legal qualification for indiscriminate poisoning. Frequent instances of the truth of this are being brought to the notice of the profession, and one such has just been reported to us, more than usually execrable. A correspondent informs us that a patient recently came to his surgery exhibiting all the signs of morphia poisoning, pupils extremely contracted, brown tongue, nausea, drowsiness, giddiness, frontal headache, and constipation. Inquiry elicited that the man had taken within three days two boxes of Keating's cough lozenges, the directions enclosed with which contain the assertion that no deleterious ingredient is contained in the preparation. In the face of the evidence afforded by the condition of the patient, there can be no doubt that he was actually poisoned by morphia; and the evils daily occurring in connection with the indiscriminate use of patent medicines leads us to insist on some preventive measure in the interest of that large section of society to whom the rough and ready remedy commends itself.

### "Time" on "Our Doctors."

Under the pseudonym of Dr. Peter Parson, Dr. Priestley is the second subject dissected by the pen of the essayist in *Time*. It is less the physician, himself, however, than the nature of his practice, and the manner and appearance of the patients who crowd his consulting rooms, that are sketched. The doctor is described as "the typical ladies' doctor," and is asserted, a little irreverently, to dispense with the services of a secretary, being "content to bell the cat himself" in respect of receiving the two guinea fee for a first consultation; and further, we are told, he follows "the manner of his most illustrious predecessors, preferring the indignity of dealing, as it were, over the counter to submitting his patients to other male eyes before encountering his own." The greater part of the essay on Dr. Parson is taken up with a description of the people who may any day be found waiting their turn to see the consultant; and it must be admitted that the fidelity of the study is something remarkable. Do we not know the mute, steady expectancy which strives to appear a simple unconcernedness and which marks the pose and expression of the occupants of waiting-rooms? There is something, too, peculiarly happy in the ease with which our writer "hits off" the special features of the places he describes. For instance, the details of the house and its internal arrangements, which are so familiar to those who have the good fortune to enter it, are all depicted with a cunning skill. The physician himself is outlined in a few words but here again we note the deep appreciation of scientific excellence which we formerly said distinguished these papers. There is a light description of a few personal characteristics, but there is an under-current of hearty reverence for the skill and learning that constitute the physician's claims to be a gynæcological specialist.

### Prospects of Legislation.

In the House of Lords on Friday last some encouragement was afforded to those who still preserve the hope that the present Parliament will do something to rescue medical education from the chaos into which it has descended. The Duke of Richmond and Gordon, in reply to Lord Ripon, said the Medical Bill passed in the Upper House last year would be introduced into the Commons, and that the Government anticipated it might become law in the present session.

### Institute of Chemistry Prizes.

A prize of twenty-five pounds is offered through the Institute of Chemistry "for the Best Original Investigation on Special Reactions of the Alkaloids, and their Separation from Organic Mixtures." The prize is given by Dr. C. Meymott Tidy, and may be competed for by associates of the Institute, and all persons who, before the close of 1880, have qualified for the Associateship in all respects short of passing the prescribed practical examination, in lieu of which latter, successful competition will be accepted. A prize of £50, under similar conditions of entry, is offered by Dr. Frankland, for the "Best Original Investigation involving Gas Analysis." We venture to think that Dr. Tidy would quite as well have served the interests of medicine if he had managed to secure the consent of the Institute of which he is a Fellow, to an *open* competition for the prize given by him. It may be necessary to stimulate the younger chemists to ally themselves with the rival of the Chemical Society, by means of prize entries to its chambers; but when a prominent member of the medical profession lends his name to a scheme such as that announced, he should take care that professional interests are conserved. There can be no doubt that there are very many medical students who might be willing and able to enter into competition for Dr. Tidy's bonus. Dr. Tidy's connection with the students of the present, should lead him to defend their interests in the matter.

### Death of Dr. Gibson.

Late advices record the untimely death of Dr. George Gibson, Surgeon on the Naval Medical Establishment at Port Royal, Jamaica. The deceased was trying a young horse, when he was thrown to the ground, and received such injuries as resulted in death. Dr. Gibson graduated M.D. at Dublin University in 1878, M.B. 1871, and was a Licentiate of the Royal College of Surgeons, Edinburgh. He was much liked abroad, and his loss will be felt by a wide circle of friends.

### The Naval Medical Service.

The condition of the Medical Service of the Navy could scarcely be worse than it is at present; but great hopes are entertained that the new Director-General will effect a speedy and material change. He cannot, however, in the absence of official warrant do very much in this direction, and it seems as though the Admiralty were still hesitating how far they even now can temporise rather than act. A correspondent writes to the *United Service Gazette* in these words:—"The Admiralty have endeavoured to maintain a reserve at the ruinous cost and involuntary sacrifice of the officers. Old age, sickness, death, and non-entries now threaten the destruction of the source of supply. The time has therefore come when the whole conditions of service in the Navy must be revised for medical men, and it is only too apparent young surgeons will not enter to drift into this reserve, regulated by its present desolating rules."

## Local Temperature in Cerebral Affections.

In presenting before the Academy of Medicine of Paris, the thermometer used by M. Voisin in taking cerebral temperature, M. Peter said that M. Voisin had proved by the use of the instrument that there was no functional cerebral trouble whether from hysteria, dementia, or any other cause, without increase of temperature, sometimes to a considerable extent. In a case of hysteria, for instance, the cerebral temperature was 41° C., while in the axilla it was only 37° C.

## Propagation of Arthritis by the Lymphatics.

M. Verneuil has published a small work on arthritic affections of the knee consecutive to lymphangitis of the lower limb. These cases are somewhat important, since there are some hydrarthroses which easily pass into a purulent condition. The fact is not confined to the region of the knee, but may show itself in other articulations. M. Verneuil has under his care, at this time, a patient who as the result of a lymphangitis of the arm has had a diffuse abscess, perfectly cured by a small incision made into the serous bursa over the olecranon, and who now has a scapulo-humeral arthritis. Many articulations have indeed very intimate communications with the neighbouring lymphatics—and we know that arthritis is propagated by the veins.

## The Benzoate Treatment of Tuberculosis.

In a discussion on a paper by Professor Klebs, read before the Society of German Physicians at Prague, the method of treatment by the benzoates was opposed by Professor Halla. He based his remarks on observations and experiments made from October, 1879, up to date. Of 20 patients treated in his clinic by benzoate, both internally and by inhalation 10, have died; 2 were unwilling to undergo the treatment, and preferred to leave the hospital, 1 was dismissed for insubordination, and of the rest 2 are in such a miserable state that they must soon breathe their last. These 20 cases were purposely selected as moderate ones, those in the extreme stage as well as very slight ones being discarded. The benzoates were administered in large doses both internally and by inhalation, and were well borne, though in some cases they produced much desire to cough, and sometimes hæmorrhage. According to the charts of pulse and temperature (which were exhibited) they had no anti-febrile effect, in many cases an increase of fever even being observed. In only one case has there been an increase of body weight amounting to 4 kilos., and it is right to mention that the patients were taking very rich and nourishing diet, to which doubtless any increase in weight may be attributed.

Professor Halla values the benzoates highly, but thinks they can exercise their antimycotic effect most where, as in diphtheria, they come in direct contact by application to the diseased part. He intends to make further experiments, and will not rashly lay aside a method of treatment which in the hands of other observers has given such good results. Dr. Derblick had treated some cases in the Garrison Hospital, and had gained more encouraging results. Internally, he had administered benzoate of magnesia in 10-gramme doses and 3·5 grammes by inhalation, with the effect of diminishing fever and increasing strength.

## Cold Enemata in Fever.

Dr. Lapin has been making experiments in the clinic of Professor Manasseni, of St. Petersburgh, on the antefebrile action of enemata of cold water. The temperature having been previously taken in the fold of the axilla, at the epigastrium, and in the rectum, a cold enema was administered. This consisted of a litre of water at a temperature of 5° or 10° C. Fifty enemata were thus administered—26 to febrile patients, 12 to patients without fever, and 12 to healthy persons.

The following conclusions were deduced from the experiments (*Le Praticien*, Jan. 12th) :—

1. Cold enemata lower temperature, which lowering lasts for some time : after enemata at 10° C., the lowered temperature in the axilla did not return to its former height until after thirty or forty minutes ; that of the epigastrium after an hour ; and that in the rectum only after an hour and a-half. When the enema was at 5° C., the lowering of temperature lasted still longer, forty to fifty minutes, or even more in the axilla, two hours to two hours and a half at the epigastrium and in the rectum.

2. Enemata at 10° C. are always well borne, and often leave behind them a refreshing feeling which extends through the body. Enemata at 5° C., are only well borne by some individuals ; in others they cause disagreeable sensations in the abdomen, and in cases of recurrent fever may cause shivering.

3. The lowering of temperature is more marked in febrile patients than in those without fever. This lowering varies in the former from between 0·60° and 0·40 in the axilla, 1·5° at the epigastrium, and 5° to 1·7° in the rectum. In non-feverish subjects the diminution is only from 0·40° to 0·30° in the axilla, from 1·4° to 1·3° at the epigastrium, and from 2·60° to 1·40° in the rectum.

4. Not only is the temperature lowered, but the pulse and respiration are reduced in frequency.

5. The lowering of temperature is most marked in the rectum, less pronounced at the epigastrium, and least in the axilla.

6. One advantage of cold enemata as adjuvants of other antipyretic agents is that they may fulfil other indications besides their antifebrile action. They soften the fæces, diminish meteorism, and facilitate the intestinal movements. Up to a certain point also, they diminish the afflux of blood to organs in the vicinity of the rectum, especially the uterus and bladder.

7. The stools appear at a variable time after the injection, from two to two and a-half minutes.

8. Cold enemata may therefore be used, even in patients without fever, when we desire besides emptying the intestine, to obtain a tonic action on it, or when we wish to diminish congestion of the pelvic organs.

## A Good Tapeworm Remedy.

DRS. R. ELBEN and J. MAINZER, of Stuttgart, in the *Wurt. Cor. Blatt.*, report excellent results from the administration of the etherial extract of filix mas, or male-fern, in 10 gram (ʒiij.) doses, for the expulsion of tapeworm.

Dr. Elben was first led to use it in the following way: After having administered 20 grams of kousso to a patient suffering from tapeworm, a large portion of the worm was expelled, but no head could be found, and in about six weeks small pieces began to make their appearance again. He next determined to try the fresh pomegranate root bark, when the patient requested his permission to try the secret nostrum of the tapeworm specialist Lutze, of Braunschweig, to which, for several reasons, he consented. The patient received two vials, the contents of which were to be taken one immediately after the other, before breakfast, in the morning. The tapeworm passed away, with its head, causing no pain or distress. Dr. E. now had the medicine analysed, and it was found that one of the vials contained 10 grams of ext. fil. mar. æth., and the other 15 grams of ol. ricini with a little raspberry juice. He afterwards obtained similar results with an extract prepared by a druggist in Stuttgart, and Dr. Mainzer likewise succeeded in ridding himself of a tapeworm after having failed with kamala and pomegranate. Both earnestly recommend it to the profession for trial.

The following directions accompany each package containing Lutze's tapeworm remedy.

The remedy should not be taken during the menstrual period or during any severe illness. In the evening, before taking it, the supper should consist of oatmeal gruel, and a cup of wormwood tea with a tablespoonful of Epsom salts should be drunk. The remedy must be taken before breakfast in the morning. The contents of vial No. 1 (ext. fil. mar. æth. ʒiij.) should first be swallowed, after having warmed it a little, and vial No. 2 (ol. ricini, ʒivss.) must be taken two minutes afterwards. After the first stool, another cup of wormwood tea with Epsom salts should be drunk. A cup of coffee without milk or sugar may be taken immediately after the medicine, or a lemon may be sucked, to remove the disagreeable taste.

## Ablation of the Larynx, Pharynx, Soft Palate, both Tonsils, and Base of the Tongue.

As *Le Praticien* remarks, after reading this long title one feels inclined to add "etc., etc."; and it is impossible to avoid remembering Professor Verneuil's outspoken condemnation of the operating mania. Yet this extraordinary mutilation has apparently been successful. The operator was Dr. Azzio Cazelli, who received for the feat the gold medal of the Academy of Medicine of Bologna. The patient was a young woman, æt. twenty, suffering from epithelioma of the parts named. We may observe that such an epithelioma is very rare at that age.

After the administration of chloroform, Dr. Cazelli commenced by performing tracheotomy by means of the galvano-cautery. He then proceeded to denude the larynx, which he carefully isolated and removed, with the cricoid, by the galvano-caustic loop. He then detached the pharynx as far as the tonsils, and amputated it; then divided the hyoid bone, removed the base of the tongue, penetrated the cavity of the mouth, detached the soft palate, and lastly excised the entire pharynx and both tonsils.

The treatment consisted in deep suture of the hyoid muscles, the employment of the œsophageal bougie, the maintaining in the larynx of Trendelenburg's canula, and union of the two upper thirds of the wound.

The operation, performed in accordance with Lister's plan, lasted three hours, and the loss of blood, thanks to the galvano-cautery, was almost *nil*. During the whole time the respiration, pulse, temperature, and colour of the face were satisfactory. A young Nice physician, Dr. Conguet, has just inquired of Dr. Cazelli, a fellow-student of his, with respect to the patient. The young surgeon informs him that he has been able not only to adapt to the patient a caoutchouc tube to replace the œsophagus, but that he has managed to invent an apparatus enabling her to articulate sounds.

THE proprietor of Siegel's curative syrup offers to any chemist who will purchase a gross of his preparation a plated cake-basket of handsome design.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Wolverhampton 16, Portsmouth 21, Sheffield 21, Bradford 24, Sunderland 25, Bristol 25, Norwich 25, Edinburgh 25, Birmingham 26, Glasgow 26, Leeds 27, Newcastle-upon-Tyne 27, Brighton 27, Leicester 29, Oldham 30, Nottingham 30, London 31, Liverpool 32, Plymouth 32, Salford 32, Manchester 35, Hull 35, and the highest rate 49 in Dublin.

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns, were—in Calcutta 33, Bombay 35, Madras 38; Paris 36; Geneva 33; Brussels 33; Amsterdam 39, Rotterdam 35, The Hague 29; Copenhagen 30; Stockholm 22; Christiania 13; St. Petersburgh 45; Berlin 25, Hamburg 29, Dresden 21, Breslau 32, Munich 35; Vienna 29, Buda-Pesth 37; Naples 29; Venice 42; Alexandria 40; New York 24, per 1,000 of the various populations. Small-pox caused 56 deaths in Paris, and 9 in Vienna.

LAST week the death-rate from the seven principal zymotic diseases in the principal large towns ranged from 0·0 and 0·4 in Wolverhampton and Portsmouth, to 9·7 and 11·2 in Plymouth and Hull. Whooping-cough showed the largest proportional fatality in Salford, Plymouth, and London; measles in Hull, Plymouth, Nottingham, and Leicester; and scarlet fever in Norwich, Dublin, and Sunderland. Ten deaths were referred to diphtheria in London, 2 in Dublin, and 3 in Birmingham. Small-pox caused 12 more deaths in London and in its outer ring of suburban districts, 2 in Dublin, but not one in any of the other large towns.

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Health of Edinburgh.—For the week ending Saturday the 31st ult. the mortality in Edinburgh rose from 89 to 110, giving a death-rate of 26 per 1,000. Chest diseases proved fatal in 58 cases, and zymotic diseases in 8. Only one death from fever was reported.

The Mortality in Glasgow.—The deaths in Glasgow for the week ending Saturday the 31st ult. were at the rate of 26 per 1,000 per annum, against 26 in the preceding week, and 29, 25, and 25 in the corresponding periods of 1879, 1878, and 1877.

Prevalence of Diphtheria in Inverness.—A special meeting of the Inverness Police Commissioners was held on the 4th inst., Bailie Macdonald presiding. Councillor R. Macdonald made a long statement, in supporting a motion asking that inquiry should be made as to the alleged impurity of the water supplied to the town, and whether the prevalence of diphtheria in the burgh could be traced to that source. It was, he said, undeniable that the purity of the water had been called in question by many of the consumers, and it was equally certain that diphtheria had for some time been prevalent in all parts of the town. After consideration it was unanimously agreed to inquire into the character of the water supply.

Birth in the Street, in Calton, Glasgow.—At an early hour on the 6th inst. a woman was delivered of a child, in the Calton, under the following unfortunate circumstances. About one o'clock a woman named Janet Anderson, or Porter, aged thirty-eight, was observed in George Street East, in a state of some distress, and around her there were three crying children aged respectively two, six, and eight years. Her condition being apparent, the aid of several matrons was called in, and not too soon, for shortly after their appearance on the scene the poor woman gave birth to a male child. Mother and baby were removed to an unoccupied house close by, and medical and other assistance were at once procured from the police office, until the parochial authorities were communicated with. Mother and child were conveyed to Bamhill Poorhouse in the course of the forenoon.

Leith.—Death from an Overdose of Laudanum.—Early on the morning of the 2nd inst. Morrison Edmond, warehouseman, died in Leith from an overdose of laudanum, which he had bought from a druggist, and had taken to alleviate pain.

Greenock Medical Aid Society.—The annual meeting of this Society was held in the Temperance Institute on the 4th inst., Dr. Marshall in the chair. The secretary, Mr. William Auld, read the annual report, which stated that during the year the Home had been removed from Union Street to a self-contained cottage in Roxburgh Street, which had been found much more suitable than the old premises. There had been two deaths in the Home during the year, and there were now in it five inmates, four of whom had been discharged from the infirmary as not likely to improve. The total expenditure for the year was £279 11d. 4d., but notwithstanding the increase in subscriptions and various handsome donations received, the income had fallen short of the expenditure by £32 12s. 9d. It was feared that unless the subscriptions came up things would fall behind still more.

West of Scotland Hydropathic Company.—The directors of this Company have appointed Dr. George Lade, Consulting Physician to the Priesstnitz House, London, to be manager of their establishment at Kilmalcolm.

Registrar-General's Returns.—According to the return of births, deaths, and marriages for the week ending with Saturday, the 13th inst., the death-rate in the eight principal towns was 26·8 per 1,000 of estimated population. This rate is 2·0 under that for the corresponding week of last year, and 1·6 above that of the previous week of the present year. The lowest mortality was recorded in Perth—viz., 19·5—and the highest in Paisley—viz., 36·1. The mortality from the seven most familiar zymotic diseases was at the same rate as in the preceding week—viz., 3·4 per 1,000. Hooping-cough was again the most fatal of these diseases, having caused 38 deaths, of which 25 occurred in Glasgow. Eleven deaths from violence recorded in Dundee were the result of the Tay Bridge accident. Acute diseases of the chest caused 187 deaths, being almost the same number as was recorded the previous week. The mean temperature was 40·3°, being 8.0° above that of the corresponding week of 1879.

Edinburgh Royal Dispensary.—The annual general meeting of this institution was held on the 31st. ult., Bailie Rowatt presiding. Mr. Robert C. Gray, S.S.C., the newly-appointed Secretary read the annual report of the managers, which stated that no fewer than 10,684 persons had during the past year received entirely gratuitous medical advice and assistance, while, at a cost to the institution of £145 19s., they had received without cost to themselves, medicine, bandages, &c. Not only were 7,220 patients, exclusive of 1,686 vaccinations, midwifery, and other cases, prescribed for at the dispensary, but 1,778 patients unable to come to the institution were attended at their own homes. The total amount of subscriptions was only £75 2s. 7d., and it seemed to the managers that even with the many demands upon the public, this state of matters simply required to be known to insure an immediate and hearty response to the appeal for increased support. In the absence of Dr. James Andrew, Mr. Gray also read the medical officer's report to the managers, which gave details as to the kind of cases treated. The treasurer reported that the income from all sources for the year was £307 1s. 11d., and the expenditure £343 1s. 3d. The chairman, in moving the adoption of the report, spoke of the great amount of gratuitous labour bestowed on the sick poor by the medical gentlemen of the city, and said they deserved the warmest thanks of the community.

Edinburgh.—Lessons on Sick Nursing.—The first of a course of lectures on sick nursing was delivered on the 4th inst., in Edinburgh, to a large audience of ladies, by Miss Pyne, of the Royal Infirmary. The Albert Gallery Hall has been engaged for the course.

# Correspondence.

## THE RADICAL CURE OF SUPERFICIAL VARICOSE VEINS BY INJECTION OF A SOLUTION OF TANNATE OF IODINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The number of procedures in use to obtain the radical cure of varix is considerable; but the most of these operations, founded very often on false theories, expose the patient to grave dangers; thus are they for the most part rejected, and not without reason. Two surgeons in France contributed to this result, Bonnet, of Lyon, and Verneuil. The latter described minutely the pathological anatomy of this affection, and in showing the real and original seat of the disease in the deep veins, proved how useless it was to expect a radical cure by attacking the superficial vessels alone. Bonnet, *à propos* of the treatment, declared that all operations should be conducted in such a manner as that the air would not come in contact with the wound. To arrive at this result he invented *cauterisation*. Later, thanks to the active ingenuity of the Lyons surgeons, the injection of a coagulating fluid into the vessels was adopted, the liquid used being generally muriate of iron. But the inconvenience, sometimes very serious, that attended and followed the injection of this liquid made M. Delore, of Lyon, seek for another fluid which, while having the same properties, as far as coagulation is concerned, would not be so uncertain or dangerous in its action. He was fortunate enough to find it in a solution of tannate of iron, which he calls "liqueur iodo tannique." This solution is prepared by rubbing together in a porcelain mortar until entirely dissolved, seventy-five grains of iodine and eleven drachms of tannic acid in thirty-three ounces of water, the latter to be added gradually. The solution is effected in a very short time, the iodine uniting readily with the tannic acid. It is then to be filtered and evaporated down to three ounces, when the preparation is ready for use. To inject this liquid an ordinary Pravaz syringe is all that is required, and the amount to be injected at one time is from *five to seven drops*, but sixty drops or more have been used without producing any evil consequences; however, in most instances the former dose will suffice. Three or four injections might be made on the limb at the one sitting if required. In operating the surgeon should take care to push the needle of the hypodermic syringe a little way under the skin before piercing the vein, on the principle of the valvular incision for the opening of cold abscesses. To be sure that the needle has effected an entrance into the vessel, the glass part of the syringe might be unscrewed, and immediately blood will appear. The operation finished, a bandage should be put on above and below the wound in order to prevent the displacement of the clot, while over the wound itself a piece of cotton is laid, fastened down by a strap of adhesive plaster. The patient is then put to bed, and not permitted to rise before the fifteenth day, when the cure is complete. In about twelve hours after the operation the usual symptoms of phlebitis appear, the pain in some cases being severe, but is eased by poultices. After the fifth day the inflammation abates, and on about the eighth it has subsided. The first few hours after the injection, and while the first symptoms of phlebitis are appearing, the clot can be felt under the skin; but under the violence of the inflammation it seems to disappear, but reappears about the eighth day, presenting the size of a pigeon's egg. The days following it diminishes little by little until the fifteenth day, when it is reduced to the size and hardness of an almond. This little tumour remains a long time stationary, several months being necessary for its complete disappearance.

M. Delore, who has operated on over sixty patients by this method, declares that his success in each case was complete. Three cases, it is true, caused some trouble, but it was owing to the patients leaving the bed before the prescribed fortnight. He also states that where the varix was complicated with ulcers, as was frequently the case, the latter healed up almost magically after the injection. The advantages claimed for this solution are: freedom from any evil consequences; a harder and firmer clot than that obtained by the muriate of iron; and the cure in all cases rapid and complete. I think this method of treating varicose veins might be tried with advantage in Ireland. Apologising for trespassing on your valuable space,

I am, sir, yours, &c.,

Hastings Burroughs, L.R.C.S.I.
Surgeon to the English Dispensary, Paris.

## THE YEAR-BOOK OF PHARMACY FOR 1879.

The "Year-Book of Pharmacy," the annual publication of the British Pharmaceutical Conference, is just to hand, and appears to be compiled more carefully than usual. This book may be divided into two parts. The first is an abstract of all the contributions to pharmacy, materia medica, and chemistry, both at home and abroad, which have appeared during the preceding year. In our notice of this part of the Year-Book for 1878, we had occasion to animadvert upon the evident restricted source of information, and we think we can see a marked extension of this source in the present compilation. The abstracts render this volume an extremely useful work, not only to the pharmacist, but to the medical man. It is, in fact, almost an essential adjunct to the physician's library, as it gives him in a concise form and well indexed, information essential to his practice. This information, when given at all, is difficult to get at in the medical journals.

The most important part of the Year-Book, however, is the second, or the Transactions of the British Pharmaceutical Conference.

From a perusal of this latter part we are enabled to draw an inference as to the progress of pharmacy in this country, unfortunately that art is much behind our Continental brethren in its development. However, as long as we can single out of the pharmaceutical transactions of this country such papers as the following we need not despair.

Dr. Alder Wright's researches upon the Aconite Alkaloids are still followed up, and have become valuable and classic papers for reference. He deals in this last research with the alkaloids of the Japanese aconite roots—Atis roots—and the products of the flower, leaves, and stalks.

Mr. Thresh's paper on the "Proximate Analysis of Ginger" shows an immense amount of research, and exhausts the subject.

The same may be said of Mr. Symes' paper on the "Polarimeter and its Use in Pharmacy." An extremely valuable paper on the "Chemistry of Saponine," by Mr. Collier, gives us an insight into this curious principle, which will, in a great measure, account for the contradictory results of previous experimenters. It is followed up by a very practical paper upon the emulsifying properties of this curious body. Of many other valuable papers, those worthy of special mention are on the "Extract of Philocarpine," by Mr. Gerrard, and one on the "Chemistry of Chaulmoogra," by Mr. J. Moss.

What brings such a paper as that "Upon the Capacity of Different Organs to Absorb and Retain Arsenic in Case of Chronic Poisoning" in the Transactions of a Pharmaceutical Society we must leave to the Committee to decide; and we also think that the paper on the "Gelatinisation of Tincture of Kino" might have been left out with advantage.

We regret to see that Dr. Attfield, who has been so long and so directly associated with the success of this society, is about to retire. We hope this retirement will not militate against the good work which the British Pharmaceutical Conference is doing.

◆

## AN ANALYSIS OF RECENT ADDITIONS TO OPHTHALMOLOGICAL LITERATURE.

### By ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

*(Continued).*

In his 4th chapter (*a*) M. Landolt proceeds to devote much care and space to the subjective estimation of squint by means of the perimeter and its objective estimation by prisms, and condemns emphatically the measurement of the degree of deviation by linear scales, objecting therefore to the ordinary graduated strabometers, whether curved or straight. He urges the superior advantages of estimation of the deviation by angles as more scientific and more accurate, and describes his methods, which—if more troublesome—have certainly the merit of being more reliable.

The Lecture 5, which deals with Muscular Asthenopia and Tonometry, is somewhat bald, and contains nothing new save a suggestion for a method of testing intra-ocular tension, which, however, the author has not reduced to practical form.

In his elucidation of the subject of astigmatism, which is

---

(*a*) "Practical Examination of Eyes." By Prof. Landolt. Translated by Dr. Burnett. London: Baillière, Tindall, & Cox.

presented in a very intelligible yet precise form, M. Landolt dwells upon the universal monocular polyopia which arises from the astigmatism of the various sectors of the crystalline lens, and which was first recognised and described by Vulpian and Donders. He says:—

"It is this same irregularity in the structure of the lens which causes a luminous point to appear to us as if radiated. Indeed, is it not surprising that the luminous heavenly bodies, in spite of their spherical shape, make on the human eye, not the impression of round luminous points, but the impression of bodies with rays? From this circumstance we have the extension of the word *stellate* to all bodies presenting a similar appearance. This fact is a proof that human eyes have for all time presented the same irregular astigmatism. There are only two examples known of men having possession of their crystalline lenses that were exceptions to this rule. One was a tailor, named Schoen, of whom Alexander von Humboldt reported that the stars appeared to him as points clearly rounded. The other is in the person of one of my own pupils. Mr. D. has never been able to understand why the stars are compared to figures with radiating lines. They appear to him as luminous points without any rays. The lenses of Schoen and Mr. D. must have been constructed with great exactness, or the irregularities of the anterior surface of the lens must have been neutralised by the irregularities of an opposite kind on the posterior surface."

The chapter on the Diagnosis of Ametropia and the means of distinguishing the various causes of myopia is well worth reading, and gives the facts as clearly as is possible, having regard to necessary brevity. In treating of the influence of age on the amplitude of accommodation, which he does very comprehensively, the author deprecates the use of the term presbyopia, and includes senile loss of accommodation as a sub-head of hypermetropia; and he urges that it is a decided error to adopt any definite standard of presbyopia at a definite age, considering that "it is much better in all cases to guide ourselves, in making a selection of glasses, by the requirements of the individual, and not by any conventional ideas of presbyopia." To this creed we fully subscribe, having seen many instances in which the patient was either under or over-accommodated for his needs in deference to his theoretic position on the Donder's scale of presbyopia. At the same time we recognise the advantage of retaining, in ophthalmological nomenclature, the term presbyopia, inasmuch as it implies a clear distinction between the optical and structural anomaly known as hypermetropia and the physico-symptomatic derangement known as presbyopia.

Much care is given to the chapter on Acuteness of Vision, and the author descants upon the necessity for having regard, in diagnosis, not to the size of test type which can be distinguished, but to the size of the retinal image. He points out that the image of an object of given size at a given distance is by no means equal in the hypermetrope, the emmetrope, and the myope, although it may be produced by the same size of type, and at the same distance in each, and, inasmuch as visual acuteness is an expression of the size of the retinal image, he urges that, in careful investigation, the result should be corrected to compensate for this error. There is, no doubt, much truth in this, but as the required compensation has to be made by an optometer — an instrument the inefficiency of which is well known—we entertain suspicion that the attempted correction by its means may rather increase the error, and, therefore, that more reliable results may be obtained by accepting the test type as the standard, and, if necessary, making a small allowance for the varying size of retinal image in the various forms of ametropia.

(*To be continued.*)

## THE PHYSICIANCY TO THE QUEEN IN IRELAND.

THE interest of the profession in the selection which Her Majesty may make of her Physician for Ireland in the place of Sir Dominic Corrigan is, as may be presumed, very lively. In addition to those whose names we mentioned last week as being current amongst the profession in Dublin, Dr. Benjamin G. MacDowel, who for many years held the physiciancy to the Richmond and Hardwicke and Sir Patrick Dun's Hospitals, and the Professorship of Anatomy and Chirurgery in the University of Dublin, is spoken of as not unlikely to receive distinction from Her Majesty.

## THE LATE DEPUTY SURGEON-GENERAL PORTER.

WE understand that it is proposed to place a memorial in the chapel at the Royal Victoria Hospital, Netley, to this officer, who died as principal medical officer of the Cabul field force, at the Sherpur cantonments, on the 9th of January, 1880, in consideration of his high professional and departmental reputation, and his very estimable personal character. The following officers have been nominated as a committee to carry out the necessary arrangements:—Surgeon-General T. Longmore, C.B., president; Surgeon-Major R. Tobin, treasurer; Surgeon-Major J. Lane Notter, M.D., hon. secretary.

## THE VACANCY IN THE IRISH LOCAL GOVERNMENT BOARD.

THE appointment vacated by the death of Mr. Bellew has not yet been filled. The name of Mr. George Morris, M.P., is still mentioned as that of its most probable occupant; and it is said that he would long since have been gazetted, but that, by his election to office, the Government would be almost certain to lose a supporter in the House, for it is pretty certain that a Nationalist or Home Ruler would replace him in the representation of Galway.

By the death of Major O'Reilly, a Commissionership of Intermediate Education becomes vacant. It is hinted (and devoutly to be desired) that Mr. Morris might be satisfactorily provided for in the Educational Department, leaving the Local Government Board for a working commissioner.

## THE RIGHT OF ELECTION OF THE MEDICAL COUNCIL REPRESENTATIVE OF THE IRISH COLLEGE OF SURGEONS.

A SPECIAL general meeting of the Fellows of the College has been called by the President for Saturday next, in conformity with a requisition presenthd to him by nineteen Fellows, for the purpose of deliberating and consulting as to the elective rights of the Fellows in regard to the Representative of the College in the General Medical Council. The requisition is signed by Drs. Robert MacDonnell, Brunker, Chaplin, Stoker, and A. H. Jacob, Members of Council, and by Drs. Martin (Portlaw), Darby and Whistler, of Bray, John MacDonnell, Corley, Meldon, Cranny, Pearsall, Stack, and Browne, of Dublin, Jacob (Maryboro'), Bellew Kelly (Drogheda), and Drs. N. Duncan and Tagert.

The right of election of a representative of the College in the General Medical Council has been exercised by the College Council ever since 1859, at which time the office was created, although at that period the right of the Fellows at large was asserted, and was sustained by the best legal advice. The question has now again arisen in connection with the propositions for reform of the constitution of the Medical Council, which came last year before the Select Committee on the Medical Bills, and the arguments in support of the exercise of that right by the Fellows at large will be laid before the College on Saturday. The subject is one of extreme interest both to the Fellows of the College and to the profession at large, on whose behalf it is desired to establish the principle that the representative of a licensing body should be chosen by the free suffrages of its members and not through the indirect agency of an executive Council.

◆

## Medico-Parliamentary.

### LUNACY LAWS.

In the Queen's Speech at the opening of Parliament on Thursday last, promise was made of fresh legislation to amend and consolidate existing laws in lunacy.

### MEDICAL LEGISLATION.

In the House of Lords on Friday last, the Marquis of Ripon asked what steps the Government proposed to take this session with reference to medical legislation.

The Duke of Richmond and Gordon.—A Bill on this subject will be introduced in the other House of Parliament. A measure on the question passed your Lordships' House last year, and the Bill of the present year will be referred to the same Committee which considered the measure of last year, in the hope of our being able to legislate on the subject; but of course that will depend very much on the progress which may be made in Committee.

### OBNOXIOUS GASES.

In the House of Commons on Friday last, Mr. Sclater-Booth, President of the Local Government Board, gave notice that he intended to ask for leave to bring in a Bill to provide for the more effectual condensation of obnoxious and offensive gases.

## Medical News.

**The Cancer Hospital, Brompton.**—The annual general meeting of the governors of this hospital was held on the 4th inst., David Mocatta, Esq., in the chair. From the twenty-ninth annual report of the committee, which was read by the secretary, Mr. Jupp, it appeared that although there had been a falling off in the items of legacies and old annual subscriptions, additional interest and vitality were indicated by an increase in donations and new annual subscriptions. During the past year 1,027 new patients were received, 306 being in-patients and 721 out-patients. It was hoped that ere long greatly increased accommodation would be provided for the treatment of the patients as well as to supply increased facilities for the study of the disease. Patients were advised to present themselves in as early a stage of the disease as possible. Thanks were accorded to the treasurer, the weekly board, medical officers, lady visitors, secretary, to the chairman for kindly presiding, and all those interested in the welfare of the charity.

**Maltine.**—After an extensive trial of the maltine preparations of the Maltine Manufacturing Company in private and dispensary practice, we are convinced that it is one of the *most valuable* remedies ever introduced to the profession. Our exalted estimate of the maltine is confirmed by all of the many practitioners who have expressed to us their opinion of it. Wherever a constructive is indicated *maltine* will be found excellent. In pulmonary phthisis and other scrofulous diseases, in chronic syphilis, and in the various cachectic conditions it is invaluable. In convalescence it is a delightful and efficient cordial. We have invariably found it liked by children. The maltine wine with pepsine and pancreatine has yielded us the happiest results in apepsia and atonic dyspepsia and in general muscular and nervous debility. The preparations of maltine and hypophosphites of ferrated maltine, of maltine with pepsine and pancreatine, and plain maltine we especially commend. It is prepared in a variety of combinations. *Maltine* deserves to stand in the front rank of the constructives; and the constructives, by their preventive, corrective, and curative power, are probably the most widely-useful therapeutical agents that we possess.—*Louisville Medical News.*

**Steevens' Hospital, Dublin.**—The board of governors of this hospital met on the 5th inst. for the purpose of electing a consulting physician in the room of Dr. Burke, deceased, and two physicians, rendered vacant by the retirement of Dr. Grimshaw, recently appointed Registrar-General for Ireland, and Dr. Bookey, deceased. Dr. Grimshaw, Registrar-General, was elected consulting physician, and Dr. Tweedy, Professor of Medical Jurisprudence, and Dr. Hayes, Demonstrator of Anatomy in the school of the hospital, were elected physicians.

**Poor-law Medical Officers' Association.** — At a meeting of the Council of this Association, held on Feb. 3rd, at their rooms, 3 Bolt Court, Fleet Street, attention was directed to the hardship of the case of Mr. J. J. Terry, of Wittersham, Kent, who after upwards of forty years' service as Poor-law medical officer, was refused superannuation allowance when incapacitated for further duty. It was resolved that a communication be addressed to the President of the Local Government Board on this subject, he having promised to a deputation of Poor-law medical officers on June 12, 1876, his willingness to investigate any case of this kind which might be brought before him.

**National Hospital for Consumption, Ventnor.** — The annual meeting of governors and subscribers to this charity was held on Friday last, Viscount Eversley presiding. The report showed the receipts for 1879 to have been £8,374, and the expenditure £6,935. A donation of £1,000 (included in the above) was acknowledged from a friend, "E. P. P. J.," and also legacies amounting to £1,000. The medical report stated that 570 in-patients had been treated during the past year, and 368 had left much improved; the mortality was only 15, or at the rate of 2.63 per cent.

## NOTICES TO CORRESPONDENTS.

**An Army Medical Officer.**—Medical officers of the Army at home and foreign stations will be permitted to exchange to the same extent as combatant officers under the qualifying conditions as to promotion specified in Articles 15, 18, and 21 of the Royal Warrant of the 27th of November, 1879, clause 1 of the Army Circulars of 1880. Except under special circumstances exchanges between medical officers serving in the United Kingdom will not be permitted, unless the officers have been at least two years at their respective stations.

**Harveian Society of London.**—Thursday, Feb. 19th, at 8½ p.m. Dr. Alfred Meadows, "Cases of Gynæcology."—Dr. Broadbent, "Venesection."

**A Colonial Student.**—Bryant, Erichsen, or Gant, either of these Text-books on Surgery is good, will be a reliable guide during your student career, and an excellent assistant after you have reached the object of your studies.

**National Orthopædic Hospital, London, W.**—The Secretary asks us to announce that the operation day at this Hospital will be changed in future from Tuesday to Wednesday at 10 a.m.

### A KNOT IN THE UMBILICAL CORD.

*To the Editor of the* Medical Press and Circular.

Sir,—I am anxious to know if any of your readers have met with a case of the following description:—

Some few weeks ago I was called to attend Mrs. G—— in her second confinement. The case was perfectly straightforward, and my patient was but a short time in labour. On the expulsion of the head, I found the cord passing from left to right over the child's shoulders. The face was much cyanosed. The uterus contracted well after the birth of the child, readily expelling the placenta, when, to my surprise, I noticed a complete knot in the cord at about 4 inches below its placental attachment. I may add that the cord in this case was not unusually long.

I am, &c.,

Inquirer.

**Dr. E. Donaldson.**—Your interesting case will appear in an early number.

**Dr. Isaac Ashe.**—1. Many thanks. 2. We shall be glad to receive it when most convenient to yourself. We are quite in accord with your opinion on their relative merits.

**Night-caps.**—A correspondent writes us, as a practical protest against the use of narcotics to obtain sleep, from which several deaths have been recently chronicled in our pages. He says: "I have been in the habit of using for some time as a soporific, a most admirable and successful 'night-cap,' against which no objection can be raised, and which in a large number of cases effects the desired end. Immediately before getting into bed, or better still, when in bed, take a breakfast cup of hot beef-tea, that made from half a teaspoonful of Liebig Company's Extract of Meat. This soothes and settles the stomach, allays brain excitement, and induces sleep."

**Royal College of Surgeons of England.**—This day (Wednesday), at 4 p.m., Prof. Parker, "On the Structure and Functions of the Vertebrate Skeleton."

**Hunterian Society.**—This (Wednesday) evening, at 7½ o'clock, Annual General Meeting for the Election of Officers.—8 o'clock. Hunterian Oration, by Dr. Pye-Smith.

**Royal College of Surgeons of England.**—Friday, Feb. 13, at 4 p.m., Prof. Parker, "On the Structure and Functions of the Vertebrate Skeleton."

**Quekett Microscopical Club.**—Friday, Feb. 13, at 8 p.m., Conversation and Exhibition of Objects.

**Hunterian Society.**—Friday evening: Annual Dinner at the Albion, Aldersgate Street.

**Clinical Society of London.**—Friday, Feb. 13, at 8½ p.m., Mr. Henry Morris: "Traumatic Salivary Fistula treated by passing a fine Catgut Bougie from the Mouth along Stenson's Duct."—Mr. Hulke, "On a Case of Sutural Union of the Median Nerve in the lower part of the Forearm five weeks after division by a broken glass bottle, followed by return of function."—Dr. Sangster: "Disturbed Nutrition, with Suppuration and Exfoliation of the Nails, probably of Strumous origin."—Mr. Heath, "On Two Cases of Popliteal Aneurism Cured by the Application of Esmarch's Bandage."

## APPOINTMENTS.

**Burd**, G. V., M.R.C.S.E., L.R.C.P.Ed., House Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital.

**Cleghorn**, Dr. H., an Additional Examiner in Botany at the University of Edinburgh.

**Grimshaw**, T. W., M.D. Univ. Dub., F.K.Q.C.P.I., Consulting Physician to Steevens' Hospital.

**Gulliver**, G., M.B., Resident Assistant Physician to St. Thomas's Hospital.

**Hayes**, R. A., M.D. Univ. Dub., F.R.C.S.I., Physician to Steevens' Hospital.

**Kenny**, J. E., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the North Dublin Union Workhouse.

**Mullins**, E. A., L.K.Q.C.P.I., L.R.C.S.I., re-appointed Medical Officer and Medical Officer of Health for the Bangor Dispensary District of the Belmullet Union, co. Mayo.

**Myles**, Mr. H. G., Resident Apothecary to the Hospital for Incurables, Donnybrook.

**Noble**, C. J., L.D.S., R.C.S.E., Dental Surgeon to the Hospital for Consumption and Diseases of the Chest, Brompton.

**Powell**, B. C., M.B. Univ. Dub., L.R.C.S.I., Medical Officer to the Roscrea Dispensary and Union Workhouse.

◆

## Marriages.

**Healy—Foley.**—Feb. 4, at St. Savour's Church, Dublin, Joseph K. Healy, L.R.C.S.I., Miltown Malbay, to Mary Vincent, eldest daughter of Wm. Foley, M.D., Kilrush, co. Clare.

**Phillips—O'Reilly.**—Feb. 3, at Castletown, co. Meath, Edward Phillips, L.R.C.P.Ed., to Mary, only daughter of John O'Reilly, Esq., Brittas, co. Meath.

**Wade—Power.**—Feb. 4, at the Parish Church, Tooting, Dr. Willoughby Francis Wade, of Birmingham, to Augusta Frances, only daughter of the late Sir John Power, Bart., of Kilfane, co. Kilkenny.

**Walshe—Mulcahy.**—Feb. 2, at the Dominican Church, Waterford, John L. Walshe, L.R.C.S.I., Kilmacthomas, to Lizzie Mary, only child of Francis Mulcahy, Esq., Durrow House, Stradbally.

◆

## Deaths.

**Evans.**—On Jan. 27, at Bath, Evan Evans, M.R.C.S.E.

**Godson.**—On Jan. 19, Henry Godson, M.R.C.S.E., of Coldhurst, Oldham, Lancashire.

**Hay.**—On Feb. 2, at Porlock, Somersetshire, Richard Francis Hay, M.R.C.S.E., eldest son of W. H. Hay, M.D., of Bridport, aged 33.

**Henn.**—On Jan. 30, at Winton Avenue, Rathgar, Edmund Poole H. Henn, L.K.Q.C.P.I., aged 23.

**Kay.**—On Feb. 5, at 7 Prince's Buildings, Clifton, Mary, widow of William Kay, M.D., of Clifton, Bristol.

**Leader.**—On Jan. 28, at Keale House, Mill Street, co. Cork, John Leader, M.D., aged 72.

**McCarthy.**—On Jan. 8, at the Royal Naval Hospital, Jamaica, Dr. Wm. McCarthy, A.M.D.

**Skelton.**—On Jan. 31, at Plymouth, John Skelton, L.R.C.P.Ed.

## SCLEROSIS OF THE NERVOUS CENTRES MAINLY CEREBRAL.

By A. HARBINSON, M.D., M.R.C.S.,
Assistant Medical Officer, Co. Asylum, Lancaster.

A peculiarly hereditary form of this complaint associated with chorea has, during the past few years, come under my notice in three instances. Two of these ended fatally, and in both sclerosis of the corpora striata was found on post-mortem examination. The third case is still under treatment.

The following are the most salient features of the affection elicited by inquiries into the history of these cases.

1. It occurs from 4 to 40 years of age; affects males and females nearly equally, runs a slowly progressive course, is invariably fatal, and is always attended by increasing paresis, and more or less mental weakness or disturbance.

2. Its hereditary character. This is notorious in the district to which the families belong, and several explanatory stories, ostensibly traditional, are current, such as "the forefather of the family committed a dreadful murder, and the victim in the agonys of death called on the Lord to bring this dreadful malady on his race." These legends at all events show that its hereditary nature is popularly well known.

3. The motor manifestations. These are generally a prominent feature, usually described in such words as "he shook and was paralysed," "he shook fearfully." In rare instances there was paresis without "shaking," and in still rarer cases insanity without either. In the three following cases the motor disturbance was choreic in character, probably due to the particular seat of the lesion.

Case 1.—J. C., æt. 33, labourer's wife, was admitted into this asylum on September 3, 1873. The medical certificate of admission stated that "she is the subject of chorea, and is frequently violent in her conduct to others. . . . . . Her language is indecent, and her habits immoral."

On admission she was described as "in poor bodily health and somewhat emaciated. There is general spasmodic action of the limbs producing choreic movements, and there is considerable twitching of the facial muscles succeeded by a vacant look. The movements of the upper limbs are at one time simultaneous, at another alternate with twisting and contortion of the hands and fingers. The lower limbs are sometimes dragged, but are capricious in their movements. The tongue can be protruded by an effort, and the articulation is somewhat impeded, pupils equal, mental faculties much enfeebled." The muscular action was deliberate, without trembling or oscillation, and produced complete movements of flexion, extension, &c., in succession and in every possible combination. In picking up a pin the hand and arm would go through all sorts of fantastic manœuvres and gyrations, but would seldom be plucked in an opposite direction to that desired. The movements ceased when she was *completely* at rest—emotionally and otherwise, but recommenced on the slightest movement or nervous excitation.

At first she could walk about and feed herself with difficulty, twisting, twitching, and jerking in a very grotesque manner. After a time decided muscular weakness was added to the motor disturbance, she lost weight, began to cough, and her condition slowly deteriorated. Her gait became more uncertain, she was less able to execute any purposive act, and was a more passive slave to the capricious movements which continued up till her death without material alteration. Increasing helplessness and paresis, together with pulmonary tuberculosis, confined her entirely to bed for the last year of life, during the latter half of which deglutition became seriously embarrassed. What little intelligence she possessed at first became gradually more clouded, until finally she answered "yes" and "no" indifferently to all questions.

Various modes of treatment, including arsenic, quinine and iron, cod-liver oil and phosphorus, chloral and bromide of potassium, and ether spray to the spine, were adopted from time to time during the progress of the case, but without any appreciable benefit. She died on October 11, 1878, five years after admission.

*Autopsy*, 10 *hours post-mortem*.—Both lungs tubercular, at the lower border of left base, a gangrenous patch the size of half a hen's egg, surrounded by a margin of condensed white tissue—close beside it an apoplexy with plugged vessels—higher up a cavity size of a pea, containing mucilaginous matter, and a collection of round calcareous granules. Pericardium contained 1 oz. of straw-coloured serum. Heart 5 ozs., frothy bubbles of gas in right auricle—cavities full of white clot, very adherent to walls. A few vegetations the size of pinheads on margins of mitral valves; calcareous degeneration at the attached borders of aortic valve, and some atheroma at origin of aorta; some cutaneous branches of the internal mammary artery, utterly rigid and calcified. Blood coagulated in all the organs. Left kidney contained small infarction white in centre, with darkly congested outer zone.

Calvarium dense, of normal thickness. Encephalon, 39½ ozs. Arachnoid and pia mater opaque, and strip readily, convolutions normal. A small neuroma in anterior region. The caudate nucleus of each corpus striatum was small, flat, and wasted, slightly increased in consistence, of a greyish or yellowish brown colour and translucent gelatinous appearance. On section, its thickness from above down was reduced to ⅛ of an inch in the anterior part (about half its normal thickness), while farther back it tapered rapidly and disappeared altogether. The outer nucleus seemed of normal dimensions.

Microscopic sections of the internal nucleus were submitted to Dr. Pepper, pathologist and tutor to St. Mary's Hospital, who kindly examined them and reported the lesion to be "a good case of sclerosis."

From inquiries made regarding the history of this case it was found that the affection had appeared in five successive generations, viz.:—

1st generation—Patient's great grandfather (grandmaternal) died of it.

2nd generation—Patient's grandmother (maternal) died of it. Two sisters and one brother unaffected.

3rd generation—Patient's mother and mother's six sisters and four brothers died of it. There were two others in the family—one healthy, the other died of consumption.

4th generation—Patient herself was one of a family of five, of whom one was a criminal lunatic. "He became imbecile, and fearfully choreic." The other four (1 male and 3 females) all died in this asylum, three of them choreic. The fourth appears to have been paralysed, with little or no chorea. One had a family, healthy but young. Another had 13 children, of whom 8 died in fits. The other two not recorded. Three of the patient's cousins (2 males and 1 female) died of the complaint, as did also four other male relatives (probably cousins). Three other cousins are ill at present—one of them is the mother of four children who "seem to possess little mind;" another is the subject of Case 3. The third is brother to the latter. He is 32 years of age, and has been choreic for 6 years, but is able to work still. One of his children, æt. 4, is affected, and constitutes the

5th generation—"He shows it quite plain."

A few cases of insanity occurred as well, for "there are other branches of the family that were very singular in their ways. Three individuals committed suicide—two by hanging, and one by cutting his throat. The woman M. R. (the subject of the following case) is descended from one branch."

Case 2.—M. R., æt. 44, a cooper's wife, was admitted January 15, 1875. She had enjoyed fair health until the present illness began, never had rheumatic fever, but for some years suffered much from headache. Her family consisted of 11 children, of whom 7 were living and healthy, the youngest being 6 months old.

The medical certificate described her as "choreic, and of weak mental capacity, excitable, very quarrelsome, frequently violent, often noisy and abusive, and under the impression that all about her are unkind to her."

On admission she was spare and weakly, but able to get about and take quiet exercise. There was no lung or heart disease. Common sensation was not appreciably affected, nor were the special senses. The motor disturbance partaking more of the character of chorea than of sclerosis or other affection, was general and of considerable severity at first, the movements being sudden and jerking, and without tremor, rhythm, or order. In walking the legs would be jerked and drawn in every direction, the body at the same time undergoing all sorts of contortions. On any emotional excitement, to which she was very prone, her whole person formed a curious spectacle of violent, disorderly, muscular agitation. The motor symptoms had existed, more or less, for five or six years and for a considerable time before any mental symptoms were observed. Speech and deglutition became progressively affected, the former high-pitched, explosive, uncertain, uncontrollable, and ultimately unintelligible, while the latter for several months previous to death was so bad as to involve considerable responsibility in feeding her.

Her mental condition described accurately above, underwent but little change. She grew more peevish, noisy, and clamorous, but her intelligence, although considerably weakened, continued pretty uniform. Notwithstanding a liberal dietary, and an insatiable appetite, she became more emaciated and debilitated, and her condition went slowly from bad to worse. With advancing paresis the motor symptoms became more harassing and ungovernable, while any feeble attempt at voluntary motion, or more especially any emotional excitement, gave rise to a distressing exhibition of muscular agitation, often so exhausting as to cause copious perspiration. Worn out by the nearly constant muscular activity, chronic abscesses and whitlow added further to the prostration, and she died on January 29, 1879.

Treatment by Peruvian bark, quinine, and arsenic was of no benefit. Conium seemed of slight use as a sedative, but not otherwise.

*Post-mortem Examination*.—Both lungs emphysematous, left slightly congested, old adhesions of both pleuræ. Heart normal, 7½ oz. Only one patch of atheroma in aorta near iliac bifurcation, but small vessels much affected and some cutaneous branches of the internal mammary extremely degenerated.

Calvarium dense with little diploë, very thick in front, and not filled by the brain, which weighed 37½ oz., thickening and opacity of membranes, which strip readily, much sub-arachnoid fluid, wasting of convolutions; ventricles dilated and full of serum. Internal nucleus of each corpus striatum markedly flattened, and deficient in plumpness, about ⅛ of an inch in its thickest part, of a greyish or yellowish tinge and gelatinous appearance, through which the white peduncular fibres could be seen. Vessels pretty healthy, those in lumbar region of the cord congested; other organs apparently normal.

Microscopically, the appearances of the internal nucleus were those of sclerosis in a less advanced stage than in the preceding case. In addition to this, Dr. Pepper found in sections of the cervical cord "diminution in number and size of ganglion cells in grey matter (anterior cornu), and also sclerosis of central part of grey matter."

*Hereditary History*.—Patient was one of a family of 10, of whom 3 became choreic and weak-minded, viz., patient herself, a brother who died at 42 years of age, and another brother, aged 35, who is ill at present. A brother became weak-minded at 17, and was drowned in consequence. Of the other members of the family, two died of unknown causes, one of consumption, one of "water on the brain," and two sisters are living and healthy. Her father (who was a patient here), and his brother, sister, and cousin (male), were affected like M. R. Beyond this point the hereditary history becomes the same as that of the preceding case, some common relatives, subjects of the affection, already described in Case 1, uniting the two families. Although "in fact they were as to their forefathers one family," I have hitherto been unable to ascertain the precise relationship.

Case 3.—D. T., æt. 25, single, servant, was admitted July 30, 1877, on the following medical certificate: "She has a vacant expression, and is of low mental capacity, and subject to paroxysms of excitement and violence; she is scarcely able to take care of herself, being afflicted with chorea."

Her father's family history is good. Her sister and mother died of consumption. Her brother and his little son are affected like herself, as were also her maternal grandmother and great grandfather, as described in Case 1.

The causes assigned for her illness are, in addition to the hereditary predisposition, an aggravated matrimonial disappointment and the subsequent birth of an illegitimate child, followed soon afterwards by an attack of small-pox.

She has always been rather weakly and delicate, but on the whole wiry and tolerably healthy. Her health and condition have scarcely altered since her admission. She is spare and ill nourished, but free from lung or heart disease, and as yet there is no decided paresis.

There have been no troubles of the special senses, or of ordinary sensation, except in the direction of slight hyperæsthesia. (Hammond mentions cutaneous hyperæsthesia as an occasional symptom of cerebral sclerosis). With her eyes shut she can touch any part of her face with tolerable accuracy. She complains of "rheumatic pains" in her limbs and joints; but it is difficult to get a reliable description of them from her.

The motor disturbance is of a mild but decidedly choreic character, and entirely devoid of tremor rhythm or to-and-fro movements. It is, however, manifested only during muscular action, or on nervous excitation of some sort; it can be restrained considerably by an effort of the will, and a glass of water can be carried steadily to the lips even with the eyes closed. The movements are general, but the trunk and shoulders are most affected, the face but slightly. Respiration is frequently spasmodically interrupted. The voice is monotonous, and speech gives the impression that the tongue and parts concerned in vocalisation are constrained and restricted to movements of slight extent. Each sentence is hurried as if to avoid the pause following or interrupting it. The pause seems due to spasm of the respiratory muscles, and of the parts more immediately concerned. Laughing is interrupted by peculiar stridulous inspiratory sounds.

The appetite and digestive powers are indifferent, and bodily nutrition is below par; the intellect is weakened and possessed of few ideas; there is emotional depression with an irritable, peevish, unhappy disposition; she cannot bear loud sounds or strong light, and she habitually complains of cold even in the warmest weather (her temperature is about normal). These symptoms might be taken as indicating hyperæsthesia and functional impairment due to nervous irritability and mal-nutrition.

She has no delusions apart from erroneous impressions concerning herself, her fitness for home treatment, and the unkindness of her relatives and everyone else towards her.

This patient and that in Case 1 were cousins, and the subject of Case 2 was related to both, so that the same hereditary history applies to each of the three.

Compared with multiple sclerosis of the brain and cord, or mainly of the cerebrum, the affection in the foregoing cases presents certain interesting features in regard to—

1. Heredity. By most authors this is not even mentioned. Charcot knows of one case (communicated to him by M. Duchenne) in which heredity played a certain part. Erb, in Ziemssen's "Cyclopædia," says that "hereditary influences may in many cases be regarded as predisposing to multiple sclerosis. Duchenne observed hereditary transmission of the disease in one case, and I have myself observed the same thing. Frerichs saw a brother and sister who were suffering from the disease, and a similar case has come under my own observation." Under hereditary transmission of chorea, Ziemssen gives the following note: "Huntington, of Long Island, with his father and grandfather (also physicians), says he has observed entire families of choreic persons, in which the disease was propagated until once a generation had been overleapt, when the hereditary disposition in that family ceased. In these cases the chorea began between the twentieth and fortieth year of life, attacked men and women alike, and usually led to mental disease, often associated with suicidal tendencies, and finally to death." Here the cause was almost certainly sclerosis, and the similarity of these to the foregoing cases in other respects renders this note particularly interesting.

2. The early age at which it may occur (4 years). Erb says "relatively few cases have been known to occur in children under 10 years of age." Charcot "observed it in patients aged 14, 15, 17 years." He cites a case from M. Leube, in which it affected a child at the age of 7 years. Hamilton, of New York, saw the disease begin in one case at the fifth year.

3. Its nearly equal distribution between the two sexes. Of the total 36 cases 20 were males and 16 females. Charcot has met with it more frequently in females (25 females, 19 males, in 34 cases.) Erb thinks "there is no marked difference between the two sexes." Hamilton and Hammond have seen it more frequently in men.

4. The motor disturbance. This in the three cases given above is unlike that usually present in sclerosis in that the movements resembled those of chorea more than any other complaint; they were not tremulous or oscillatory. In one case they could be somewhat controlled by the will; in two they continued up till death without decided alleviation. As in sclerosis, however, they ceased during perfect rest; they were greatly intensified by any emotional disturbance, and they affected the muscles of the face but little. Rigidity and contractures of the extremities did not occur, owing probably to the slight implication of the cord. Muscular unsteadiness appeared before the paresis (a diagnostic point, according to Hammond and Jaccoud, between cerebral and cerebro-spinal sclerosis). These cases illustrate Charcot's remark that sclerosis is *par excellence* a polymorphous affection.

5. The preference of the affection for the corpora striata, as found in two cases on post-mortem examination. This furnishes the probable explanation of the choreic character of the motor disturbance, for all authorities agree in localising the immediate cause of chorea in or in and about this region. Drs. Broadbent and Fox look upon the symptoms of chorea as pointing to the seat of mischief, not to its nature, the latter believing "that any lesion that interferes with the nutrition of this region of the brain may cause choreic jactitation, if only the interference with nutrition is not of sufficient extent to cause paralysis."

I refrain from noticing in connection with this point, the various cases of chronic chorea associated with gross lesions of the corpora striata to be found in medical journals and elsewhere, and will only in conclusion draw attention to Erb's remark regarding sclerosis, that its "differentiation from chorea minor is, as a rule, easy, since the volitional tremor differs very essentially from the choreic movements. One case that came under my own observation has, however, convinced me that the choreic motor disturbance can, like ataxia, occasionally occur as a concomitant symptom in multiple sclerosis."

## ZYMOTIC DISEASES IN DUBLIN. (a)

By Dr. J. P. NOWLAN.

Since my connection with the North City Dispensary, now past four and twenty years, the various epidemics of zymotic disease that have come under my notice have

---

(a) "Zymotic Disease as observed in No. 1 North Ci District since 1855." A paper read at meeting of the "Society of Metropolitan Medical Officers of Health" on 10th December 1879.

B

presented so many features in common, viz., their gradual approach, arriving at an acme and graduated decline, above all, the prevalence of one to the extinction of the others, have forced me to conclude that an unvarying phenomenon must imply a fixed causation. In the present day, even in the ranks of the profession we hear the cry that disease should be stamped out; the public re-echo the cry; in fact, sometimes I regard myself as a sort of medical Rip Van Winkle, who having slept several years, a medical revolution has occurred, leaving me in my waking moments behind the age. In school days, when reading Homer, in the first book of the Iliad, we read of Apollo sending a plague among the Greeks, as they sat around the beleaguered city, which is said to have attacked equally men and beasts. The world's history but repeats the tale—as the human race spread, cities and nations rose, epidemics followed often in their track. In bringing a paper like this before a Society composed as it is of men who have the same field for observation as myself—some my seniors—the idea suggested itself to me that I was performing the familiar feat of bringing coals to Newcastle. However, in reading the words of the late Dr. Stokes, when speaking on the subject of preventive medicine, I felt somewhat confident that the effort I was about to make, however feeble, had the sanction of his high authority. I will first take the epidemic of cholera which occurred in 1866. During the year 1865, it became apparent that cholera was on the march; it followed almost the lines of 1832. From 1855 to 1876 the whole line of quay, from Carlisle Bridge to the Light House at North Wall, was in No. 1 North City District; it is the great centre of the cross Channel trade. Cholera was epidemic in Liverpool in July. On the 2nd August a man and woman, arrived from Liverpool, took lodgings at 8 Mayor Street. The woman took ill a few hours after arrival, and died of well-marked Asiatic cholera. The man went down to Newbridge to see a friend of his in the Scott's Greys, then stationed there; took ill in the railway carriage. On arrival in town was brought to Green Street Hospital, and died there. It is worthy of remark that no other case occurred in this house. From the 3rd to the 7th inst. no further case occurred; on the 8th inst. three cases were reported. The first case I visited was a man named Larkin, living at Church Place; the second, at Spring Garden West; the third, at Beaver Street. It is, I think, important to fix the exact locality of these cases. To be brief, I may say, if you formed an equilateral triangle, each of these cases would represent the angle of the triangle; the sides would be about a mile in length. It struck me as strange that three men living apart should be attacked simultaneously. On inquiry, I learnt the following facts:—They were in the one employment the day before, engaged in collecting clay, used in the manufacture of bottles. Their mode of working was as follows:—They went down the river at full tide to the Bull Wall; as the tide fell the boat grounded; they then loaded the boat with this clay (found there), when the boat floated with the returning tide. They returned back; they were engaged at this work on the 7th inst., returned to their respective homes, took ill during the night. From that time forward cholera and diarrhœa became epidemic; they were treated at the dispensary—106 cases of Asiatic cholera, and 722 cases of diarrhœa; it lasted five months, assumed its acme in the third month, began to decline in the fourth, subsided in the fifth. On the night of the 5th of October I awoke with a feeling of great depression, which I could not shake off. Knowing what was about, my thoughts were not of a very pleasant character; however, I kept my ideas to myself. The night passed over without any result to myself or household. I then lived in 11 Hardwicke Street. On the following morning I learnt that in Hardwicke Lane, in a straight line across the street, a man named Fitzpatrick was attacked during the night. Further on, in a direct straight line, across Dorset Street, three cases occurred during the night in Whites Lane. At 9 o'clock each night I used to go round any cases seen during the day. On entering some streets I became sensible of a peculiar state of atmosphere, as it were breathing a heated mist, a peculiar odour. The only similitude I can think of is that peculiar smell which we find in a field of potatoes recently struck with blight. Whenever I found such a condition of atmosphere, I inferred the occurrence of cholera during the night; my gloomy forebodings were generally realised. Now the first case of cholera in Dublin occurred on the 27th July in No. 4 South City District, which contains the south line of quays from Carlisle Bridge. It is strange, a case occurred in Wexford the same day. Graves remarked that in the cholera of 1832, Wexford was the last place attacked. The cholera reached Dublin the 22nd March, 1832, Wexford 21st August, 1832. Graves attributed the fact to there being no steam communication between Dublin and Wexford, the absence of passenger traffic, the trade being only export. Steam has increased since Graves' time, and now we have the railway, bringing Wexford within a few hours of Dublin. In my district several steamers passed daily between Liverpool and the quay. The two fatal cases occurred on the 2nd, yet the epidemic did not assume its form as such until the 8th. Now I may at once say that I believe that these three men working at the mouth of the river encountered the cholera cloud as it entered Dublin. That cholera follows the line of river and the roads of commerce will not be disputed. Now it may be asked, what do you mean by a cholera cloud? I mean to say that the materies morbi is in the atmosphere; but at present I do not believe it exists as a cloud of germs or bacteria. I incline to the belief—that it exists in a gaseous form and obeys a simple law of chemistry—that it has its special solvent; as its atmospheric existence is general, its application, if elective, must be determinable. Now the atmosphere of each house is special, and may supply its solvent menstruum. Now when cholera enters a street it takes its side and special houses. I believe it finds its solvent in the air of the household, and takes its victims from the weakest, or the strongest predisposed by fear. As to the night of the 5th of October, I believe the cholera cloud passed over my house, but finding neither localisation or receptivity, passed on, and soon found its victims. As to my general experience of the choleric atmosphere, I may remark, Mr. Glaisher has demonstrated the appearance of a peculiar blue cloud, and the absence of ozone. Neither scarlatina or other zymotic prevailed during the epidemic. I will next take the epidemic of scarlatina. In 1855 I found an epidemic of scarlatina in the district. It was characterised by the occurrence of diffuse inflammation of neck, ending in destruction of the skin and cellular tissues, the muscles laid bare, as if dissected, and the occurrence of arterial hæmorrhage. In one instance two sisters died in the third week from smart arterial hæmorrhage. The blood was projected per saltum; death ensued ere any effort could be made to save them. To show the effects of constitution in modifying the disease, I attended the brother some years subsequently in another locality; he died of malignant scarlatina. In the epidemics observed by Graves he inclines to the belief that the strumous diathesis does not modify them. My experience of the epidemic since that time is that it does so in a marked manner. One example I will give. Four children in one house; three children of healthy parents passed through the disease; the fourth, a nurse child and strumous, was attacked with diffuse inflammation of the neck, and died. I invariably find the ages, two, five, and ten, as extremely fatal, and my experience in registration confirms my own observation. I believe the law of Mr. Simon in his lectures of Pathology may account for this fact. In 1871, 1874, 1876, epidemics occurred, each differing from the other, and presenting type and form distinct. In the year 1868 we were congratulated on the stamping out of small-pox in Ireland, showing the good effects of compulsory vaccination. The epidemic of 1871-72 rudely dispelled the flattering delusion. As the epidemic of scarlatina, 1871, subsided, diarrhœa set in. In September small-pox appeared; prevailed as an epidemic five months; continued on until September, 1872. During its prevalence scarlatina disappeared; in 1873 almost nil. Now lately it has been stated that the prevalence of small-pox in Dublin implies defective vaccination. That vaccination controls small-pox, and of its good effects, there can be no question; but the mitigation of small-pox and its utter extinction are two different things. For the last two years small-pox has appeared in the district, but never as an epidemic like 1871-72. As small-pox increased scarlatina decreased in a marked manner. Now I think in a well-vaccinated community small-pox is a disease easily treated. I can with perfect truth say that, having vaccinated over 5,000 people, not a single death occurred among them. Some have taken modified small-pox, but the disease was trivial, and readily yielded to treatment. Now I ask, what control have you over scarlatina?—a disease that kills in twenty-four hours; like cholera, it baffles all treatment. West, in his work on "Disease of Children," and other authorities, have pointed out, it would be well for those people to consider what the extinction of small-pox would entail. Take London for the last month; deaths from small-pox some weeks nil; scarlatina increasing from 70 to 106 per week. Week ending the 29th November as follows:—Small-pox 3; 78 from measles (an increase of 21); 102 from scarlatina. Thus wealthy London and Dublin obey the one law. I could adduce authority and figures to prove the proposition, but I think I have adduced enough at least to induce a calm consideration of the subject. As to measles, fever, I fear to enter into this subject; in fact time, and having regard to the time reasonably to be occupied in reading a paper—but I may say they would but confirm my previous observations. In 1855 typhus fever prevailed. I met with cases of large cervical abscess as a result. I have not since encountered such. Where matter formed the cases recovered, confirming the remarks of Graves. Latterly the typhoid type prevailed. Comparing the death-rate in England, Ireland, and Scotland, under these heads, localising power, receptivity, and recuperative power, I believe from all combined causes, of which we lately have heard so much, that Dublin—if I may use the expression—is tenacious of epidemics. As to receptivity, I believe Dublin has a largely acquired one. The habits of the people, above all intemperance, leads to it; but in fact everything that lowers the constitution opens the door to contagion. As to recuperative power, it follows from the above that a broken constitution cannot possess it. Sanitary authorities and our own profession may exert themselves to their utmost without effect if the community live regardless of sanitary laws. In conclusion, I have to express my regret that I had not that time at my disposal to give to the preparation of the paper which the extent of the subject called for, and to show the interest I take in this Society, which I believe is well calculated to raise preventive medicine from the present unsatisfactory condition in Ireland.

# Clinical Records.

## RICHMOND SURGICAL HOSPITAL.

### Cases under the Care of Mr. Stokes.

*Labial Epithelioma. Zeis' Cheiloplastic Operation.*

The following cases afford examples of the satisfactory results obtained after the removal of extensive labial epithelioma by Zeis' cheiloplastic operation, a procedure the details and steps of which Mr. Stokes has already described in the *Dublin Medical Journal*, 1872.

Case 1 (From Notes taken by Mr. J. Sullivan).—Garrett Leech, æt. 70, a labourer by occupation, was admitted into the Richmond Surgical Hospital on the 16th of last August, under Mr. Stokes' care. The disease was of seven years' standing, very extensive, and involved not only the entire of the red border of the lower lip, but also the tissues below this to the extent of fully one-half to three-quarters of an inch. The general health of the patient was good, and there was fortunately no evidence of glandular contamination. On August 21st, Mr. Stokes performed Zeis' operation. The edges of the flaps were united by two strong hare-lip pins at each angle of the mouth, and six fine entomologist pins were used to bring the rest of the flaps in accurate apposition.

On August 24th, Mr. Stokes removed the pins, when excellent union was found to have taken place.

On September 1st the patient left hospital, the result being in every respect eminently satisfactory. The patient's temperature throughout was normal.

Case 2 (From Notes taken by Mr. Skerrett).—Michael Ryan, æt. 56, by occupation a labourer, was admitted into the Richmond Surgical Hospital under Mr. Stokes' care on December 15, 1879, suffering from extensive labial epithelioma complicated with several enlarged sub-maxillary glands. He stated that twelve months ago a small, hard spot appeared on the lip, which was whitish in colour. This increased slowly in size, and he was then persuaded by his friends to consult a "cancer doctor," who applied a paste which in the patient's opinion had a marked effect in causing an increase of the disease. He then came into the Richmond Hospital, when it was found that the whole of the lower lip was extensively and deeply involved in the disease. A cluster of enlarged glands in the sub-maxillary region was found.

On December 17 Mr. Stokes operated by Zeis' method, and when the flaps were brought together in a manner similar to that adopted in the first case, he proceeded to excise the enlarged glands. This was accompanied with greater difficulty than was anticipated, but eventually was satisfactorily accomplished. The patient's temperature on the evening of the 17th was 100·2° F., and he complained of some pain.

On the following day Mr. Stokes applied fresh dressings, and was quite satisfied with the appearance of the wound and the progress towards union that had already been effected. The patient was suffering no pain, and both his pulse and temperature were normal.

On the 19th Mr. Stokes removed the needles and sutures, and the union was found to be perfect.

A few days subsequently an abscess formed in the situation where the enlarged glands had been removed, but was attended with little local, and no constitutional, trouble. The patient shortly after returned home, the result of the operation being all that could be desired.

# Department of Lunacy.

## SUICIDAL NICETY.

To those insane patients who contemplate self-destruction "the bare bodkin" is sometimes more deterrent than "the dread of something after death;" and in them "the native hue of resolution" is sicklied o'er by physical cowardice rather than by reflective subtleties.

A lady who was constantly proclaiming her suicidal tendencies, and was therefore watched night and day, was recently an inmate of a lunatic hospital. Her great desire was to end her life by drowning, and it was therefore necessary for three nurses to hold her when she was having the warm baths that constituted part of the medical treatment in her case, to prevent her from putting her head under water, which she frequently attempted to do. After many tiresome contentions the chief nurse, a woman of expreience and resource, feigned to be weary of the conflict, and ordering the other nurses to stand aside, told the patient that she might do her worst, as they would not interfere any further. The poor lady at once put her head under water, but as speedily pulled it out again. Several times she repeated this manœuvre. At length, seeing the nurse smile, she exclaimed, "It's no use! I could drown myself in soft water instantly, but not in nasty hard water like this." After that she did not again speak of drowning herself, nor make the most distant attempt to do so.

The incident is quoted not to suggest a method of treatment, for it would be rash indeed to allow lunatics to approach the suicidal act, in the expectation that they would finally shrink back from a close contemplation of it; nor to point the moral that suicidal lunatics as a rule protest too much, for it is wise to err on the safe side, and to regard ever what are suspected to be empty threats as if they were real determinations; but to illustrate the manner in which insane impulses are sometimes suddenly turned aside, and the curious irrational reasons that are given for the deviation.

## THE LUNACY INQUIRY COMMISSION.—III.

According to the 27th Report of the Inspectors of Lunatic Asylums, there are at present 3,365 of the insane in workhouses. As the supervision of these patients seems to be very imperfect, as they appear to have arrived in their present position in a very accidental sort of fashion, and to be, indeed, very much "nobody's children," it might have been anticipated that the Lunacy Inspectors would have found much reason to complain of the treatment and management of this unfortunate class. But exactly the reverse appears to have been the case—at least, for the last few years. We are agreeably surprised to find nearly five folio pages of the Commissioners' Report filled with notices extracted from the Inspectorial Reports of various workhouses. These are all favourable, some absolutely flattering. It may be said, "they are a selection chosen for a purpose." Even if this were true, the very fact that such notices could be culled from the Inspectors' Reports more than proves the case which the Commissioners advocate. Almost everything connected with the detention of the insane in workhouses is at present imperfect. It is confessed that due inspection is often difficult, sometimes impossible. The buildings occupied by the insane have, certainly in most cases, never either been erected for their accommodation, or subsequently modified to adapt them for that purpose. Those who have practical experience of the matter will often have noticed that a considerable number of the insane occupants of workhouse wards are but sojourners pending the commission of some slight assault which will enable them to be transferred to the nearest lunatic asylum as "dangerous lunatics or idiots." In spite of all this, the Inspectors are able to say that those patients whom they visit in workhouses are "duly attended to," are "humanely attended to," are "kindly attended to," &c. Further they praise the cleanliness and comfort of the wards, the scale of diet, the clothing and bedding, the ventilation, &c., and in several passages express themselves well pleased with the manner in which the general health of the patients is looked after.

It is evident, then, that the further provision for lunatics in adapted portions of workhouses has *primâ facie* this in its favour, that it is merely an extension with improvements of a system which has been already in work, and which, even under most disadvantageous conditions, has met with the approval of the heads of the department. But if the recommendations of the Commissioners be carried out, most of the disadvantages under which the present system works will be removed. Isolated cases of insanity will not be scattered about through workhouses in a manner which sets a thorough supervision at defiance. On the contrary, special buildings set apart and prepared for the purpose will be reserved for the reception of considerable numbers of the insane of a particular class, and it is hard to see in what way this plan will fall short of the older usage, while the facilities for complete inspection and systematic treatment that it offers are obvious.

It is scarcely necessary to remind our readers that the Commissioners do not desire to place in workhouses all the lunatics at present needing accommodation, but only those of them who can be classed as imbeciles or idiots. The space at disposal is far more than sufficient for the reception of all such who are at large and neglected, and it is recommended that the surplus room be utilised for the accommodation of the numbers of idiots and imbeciles who have drifted into our district asylums. While the Inspectors, as we have seen, are lavish in their praise they bestow upon the workhouses, there is one fault or imperfection in our district asylums, to which they are never weary of calling attention. In report after report—both at individual institutions, and in the yearly summary for the whole department—they deplore the evil of overcrowding. It is much to the credit of the Irish inspectors that they have never been inclined to look upon our public asylums merely as places of safe detention for lunatics, but have always seemed to consider that the first and most important function of these institutions is to be hospitals for the cure of the mentally afflicted. To this view they have steadily adhered under the most discouraging circumstances, and have persistently and conscientiously expressed their opinions when their voice was but as one crying in the wilderness. The attention that the Government and the public usually pay to these matters is essentially rhythmical. At the end of a long period of individual effort, public feeling is stimulated to some philanthropic outburst. This outburst is almost always ill-considered, often misdirected, and once it is over, is invariably followed by a lull, during which popular sentiment refuses to answer to the most urgent stimulant. In the case before us, when the call for some proper place, where some of the heretofore neglected lunatics could be guarded and taken care of, had at last made itself heard, decisive action was taken by the construction of a number of lunatic asylums throughout the country. When this was done it was scarcely to be expected that any further attention would be given to the subject for a few generations more. To be sure the department has increased, but, in a polypoid sort of fashion, by an "irrelative repetition of similar parts." There has been no change of plan, no improvement, no development. Not the less on this account, nor because they received no encouragement and apparently no hearing, did the Inspectors continue to deplore the swamping of the asylums by the detention in these institutions of incurable cases whereby their powers as curative establishments have been grievously crippled. The resident medical superintendents of the various asylums have confirmed the view taken by the the Inspectors, and the Commission of 1857, having reviewed the evidence of both, reported—

"At present the district asylums are, to a great degree, deprived of their utility as curative hospitals for the insane, by the large proportion of probably incurable cases which they contain;" and proceeded to recommend that portions of workhouses should be appropriated for a certain class of the probably incurable.

No action of any kind has followed this recommendation, and the evil has gone on increasing ever since. The only remedy applied to the overcrowding complained of so continually, has been to build new asylums, or additions to those already built,—in either case, at an expense which, considering the poverty of the country, may be well termed enormous, and in view of the evidence adduced before successive Commissions seems utterly unjustifiable and uncalled for.

As has been already pointed out, there are "at large" and "neglected," a very considerable number of curable cases of insanity,—cases which it is neither humane nor expedient to permit to fall into an incurable condition. All these cases could be easily provided for in our district asylums, if the latter could be relieved of their present plethora of incurable patients, and in this manner (the idiots and imbeciles at large having been accommodated in workhouse auxiliaries) the class of neglected lunatics would disappear from the country, while, at the same time, one of the most serious drags upon the efficient working of the district asylums would be removed.

It remains to consider the evidence of the medical men connected with asylums, whom the Commissioners have questioned as to the feasibility of this scheme. When the Commissioners visited Ennis, they examined Dr. Daxon, the superintendent of the asylum there, and Dr. Cullinan, the visiting physician. Both gentlemen expressed their approval of the plan, the latter indeed, claiming the credit of having made a similar proposal long ago. But more than this, "the Ennis Asylum," the Commissioners say, "is not crowded, as the harmless and incurable are drafted to the workhouses by the resident medical superintendents." In his evidence Dr. Daxon states that he has now sixty patients who could be transferred to adapted workhouse buildings.

Here then we see, that one who has tried the experiment as far as it was possible under present conditions, is so far satisfied that he is ready to go further than present circumstances permit. The superintendents of the asylums at Mullingar and Monaghan express decided approval of the scheme, while the superintendent of the Richmond Asylum, Dublin, seems also to approve of the principle on which it is framed, though personally he would prefer to see a few large special asylums (like those of Leavesden and Caterham) in place of several smaller buildings set apart for imbeciles. Sir Dominic Corrigan was a member of the Commission of 1857, whose recommendation as to the establishment of workhouse asylums has been above referred to, and we find from his evidence before the present Commissioners that he "concurs entirely with their view" in this matter, though he is far from looking favourably upon the system which scatters lunatics by twos and three's through workhouses in such a manner that they are often grossly neglected. Dr. MacCabe, now Local Government Board Inspector, formerly an asylum superintendent, also expresses himself decidedly in favour of the establishment of auxiliary asylums in connection with workhouses. We have above referred to his very remarkable evidence with reference to the working of the lunacy department in Cork Workhouse, which shows what can even now be done in workhouses under favourable circumstances and clever management.

We are not surprised, however, to find that he is very strongly of opinion that the accommodation for lunatics in workhouses in his district has hitherto been generally insufficient in quantity and defective in structural arrangement.

Again, Dr. Hatchell, one of the Inspectors of Lunatic Asylums, though he had much to say against the manner in which lunatics are at present accommodated in portions of workhouses ill-adapted for the purpose, and often so placed that sufficient inspection is impossible, seems on the whole to approve of the plan recommended by the Commissioners, and to see no insuperable difficulties in the way of carrying it out. In fine, the evidence in favour of the establishment of auxiliary asylums as recommended is very strong, while we are unable to discover that any really important objections have been brought forward on the other side.

In the work we have been reviewing, the plan for adapting portions of workhouses for the reception of imbeciles and idiots is closely associated with a further scheme recommended by the Commissioners for the division of the district asylums into two classes:—Curative hospitals and asylums for incurable cases requiring special care who could not well be treated in workhouse auxiliaries. As, however, a number of points arise in connection with this matter, which are quite distinct from those involved in the question of workhouse adaptation, we have thought it well to treat the two subjects separately.

In our next number we will return to this Report, and consider the classificatory scheme suggested.

## DANGEROUS LUNATICS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would you kindly state in your next issue, if, in case of a supposed dangerous lunatic brought before two justices, the said justices cannot *legally* accept the certificate of any medical man other than that of the medical officer of the dispensary district in which they may be at the time, or in case he may not be available, that of the nearest available medical officer of a neighbouring dispensary district? If so, is it not rather hard upon the medical attendant of the supposed lunatic who may have been called upon to visit him?

Yours, &c.,

"LUNACY ACT."

[The clause of the Act of Parliament is as follows:—"*Dangerous Lunatics and dangerous Idiots to be sent to Asylums.* 10. Whenever any person shall be brought before any two justices and it shall be proved to their satisfaction that such person was discovered and apprehended under circumstances denoting a derangement of mind, and a purpose of committing some crime for which, if committed, such person would b liable to be indicted, the said justices shall call to their assistance the medical officer, or, if there be more than one, the nearest available medical officer of the dispensary district in which they shall be at the time, and if there shall not be any such medical officer available, then the nearest available medical officer of any neighbouring dispensary district, who shall examine such person."—Ed. M. P. & C.]

## Special.

### FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, Feb. 6.

The Chamber having recently decided on the creation of an ophthalmic *clinique* at the National Hospital Quinze-Vingts, the Minister of Public Works has addressed a letter to the different railway companies inviting their co-operation as far as granting free passes to every indigent who would be desirous of entering the establishment. In return for this favour the directors of the Quinze-Vingts would engage themselves to admit gratuitously all the servants of the railway companies who suffer from eye diseases.

*Treatment of Chest Diseases by Petroleum.*—Dr. Moubré, writing to the *Gazette des Hopitaux*, gives his experience of petroleum capsules in simple and chronic bronchitis. This balsamic had been brought before the Therapeutic Society by Dr. Blache a year ago, at the instigation of a Paris chemist, who named it Gabian oil, in order to prevent public prejudice. Each capsule contains twenty-five centigrammes of pure petroleum, the ordinary oil not being used, as it has to be distilled in contact with sulphuric acid to render it fit for lighting purposes. At the Hospital Beaujon, where these capsules have been freely ordered for chronic bronchitis, a rapid diminution of the secretion and fits of coughing were observed. In tuberculosis this medicine gave encouraging results.

At the Société Medical des Hôpitaux, M. Besnier read the Quarterly Report on Current Diseases, from which it appeared that pleurisy had considerably increased, the number of cases exceeding that of pneumonia, whereas formerly there were five cases of the latter for one of pleurisy. One of the members commenting on this increase, would not ascribe the increase of mortality due to this disease as much to thoracentesis as to the augmented gravity of pleurisy. M. Bucquoy remarked that pleurisy was certainly a graver disease than pneumonia from its results, but that was not due to the puncture.

*Treatment of Aphthæ by Corrosive Sublimate.*—Dr. Vivier in the *Journal d'Accouchements*, recalls the treatment recommended long ago by Bazin, which consists in the employment of bichloride of mercury in the form of lotion for aphthæ, and which in Dr. Vivier's opinion is without comparison more efficacious than all other remedies. The following is the formula :—Corrosive sublimate, 12 grains ; alcohol 1 drachm ; distilled water, 7 drachms. A camel's hair pencil dipped in this solution and applied to the aphthous spots two or three times a day succeeds invariably in curing the sores. But this treatment has one drawback—it is that it could not be entrusted into the hands of parents, and consequently it necessitates a greater number of visits, but which, according to Vivier, is amply compensated for by the rapidity of the cure.

Dr. Haussmann publishes two observations demonstating the good effects of compresses of phenic acid on the fissured nipples of nurses. The solution he employs contains five per cent. of phenic acid. At the Lying-in Hospital, Berlin, this agent has been largely experimented on by Dr. Steiner, who has drawn up a report containing observations of forty patients who were treated advantageously by this method. However, the mode of application differed in that the solution was brought in contact to the affected nipple by means of a hair pencil, and not by compresses.

Dr. Chéron, attached to St. Lazare, recommends for epithelioma of the vagina the following injection :—Chlorate of potash, one ounce ; laudanum a drachm ; water six ounces. A table-spoonful of this solution in a pint and a-half of warm water to be used in injection twice a day.

### CLINICAL SOCIETY OF LONDON.

The last meeting of this Society was held on Friday, Feb. 13th, Dr. E. Headlam Greenhow, President, in the chair.

Mr. Henry Morris on

#### TRAUMATIC SALIVARY FISTULA CURED BY PASSING A FINE CATGUT BOUGIE FROM THE MOUTH ALONG STENSON'S DUCT.

A shoemaker came under my care in the Middlesex Hospital on June 24, 1879, for bleeding from several incised wounds, one of which was about two inches along, and vertical in direction, on the right cheek. On June 28th saliva was seen trickling from the lower end of this wound, which was all but healed. The patient now stated that since the injury the right side of the mouth had felt very hot and dry, and that he had constantly to moisten it by carrying the fluid from the left side over to the right of his mouth. A fine catgut bougie was introduced at the oval aperture of the duct, and passed onwards towards the parotid gland until it emerged on the cheek through the fistula. The newly-healed wound was laid open, and the proximal end of the injured salivary duct searched for, and found by squeezing the parotid gland until a little saliva was forced out of the duct. Into this the point of the bougie was inserted and pushed onwards for about half-an-inch. The edges of the wound were brought together with three hare-lip pins and twisted sutures, and the bougie cut short, so that a short end, not long enough to be caught between the molar teeth, was left protruding into the mouth from the slit-like orifice of the duct. The patient at once appreciated a marked difference in the feeling of the right side of the mouth, which was now in all respects like the other side, and he could distinctly feel saliva trickling into it. On July 4th the bougie came away accidentally. The wound on the cheek had been all but healed for four days, but a little discharge still escaped at its lower end. On July 9th a little saliva was escaping still ; cotton wool and collodion were therefore continued over the wound until the 15th of July. By this date the wound was securely healed, and all the saliva flowed freely into the mouth. The man was retained in hospital for a few days longer, and was then discharged well. The facility with which a bougie can be passed along the parotid duct from the mouth encouraged the author to think that the same treatment would prove successful in most cases of parotid salivary fistula, meaning by salivary fistula a fistula of the parotid duct as distinct from a fistulous communication with the parotid gland itself, such as occasionally follows abscess below or behind the ear ; and also as distinct from an opening into the cavity of the mouth, such as sometimes occurs after necrosis of the jaw, and in cancer. If the orifice of the duct, which is its smallest part, becomes obstructed after long disease, the mucous membrane of the cheek may be punctured, and then a bougie might be passed into the dilated part of the duct, which is just where it pierces the buccinator muscle, and urged along it beyond the fistulous opening. In operations for the removal of tumours of the face, when an incision must be made so as to divide the duct, it would be well to pass a parotid bougie whilst the patient is still under chloroform, so that the potency of the duct and the flow of saliva into the mouth might be secured during and after the healing of the wound.

Mr. J. W. Hulke on

#### A CASE OF SUTURAL UNION OF THE MEDIAN NERVE IN THE LOWER PART OF THE FOREARM, FIVE WEEKS AFTER ITS DIVISION BY A BROKEN GLASS BOTTLE, FOLLOWED BY RETURN OF FUNCTION.

A bottle washer, by the bursting of a Seltzer water bottle, received a deep gash across the the front of forearm, just above the wrist, which severed the median nerve, the radial artery, and several tendons. Five weeks later, on 23rd July, there having been no return of nerve function, the nerve was exposed by dissection. The ends were found ¾ inch apart, the upper bulbous, the lower pointed. Enough was cut off each end to get plane surfaces at 90° to long axis of nerve. The upper end was pulled down in order to lengthen it, and the ends were brought together by four stitches of very fine silk passed through the sheath ;

the forearm and hand were fixed on a splint. On 15th August he was discharged; sensibility had returned in the parts before numb, except the last phalanges of index and middle fingers. Later further improvement took place.

Mr. HOWARD MARSH said he hoped soon to record a somewhat similar case which had been under Mr. Holden's care. In it the nerve had been injured for some time, but there had been a recovery of function within twenty-four hours after the operation. He desired to know if Mr. Hulke had stretched the nerve, and to be told the nature of the suture employed.

Mr. HULKE said the nerve ends had been brought together with considerable force; the suture was a silk one, consisting of what is known as 3-plie China twist. It is an excessively fine thread.

The PRESIDENT remarked that the case presented many interesting features to the study of the physician.

Dr. A. SANGSTER on

### A CASE OF DISTURBED NUTRITION, WITH SUPPURATION AND EXFOLIATION OF THE NAILS.

E. K., æt. 7, came under observation October 16th, 1879. There was a history of "chest complaints" on the mother's side. The mother looked healthy; she had had seven children, three of whom had "lumps in the throat;" three died in infancy. The patient was a delicate-looking little girl; her mother brought her to the hospital for the affection of the nails, and ulcerative stomatitis. The terminal phalanx of the middle finger of the left hand was about twice its natural size, hot, red, and very painful, so that the child held the finger with the other hand in a vertical position, to keep it from being jarred. The nail was greenish-black, curved talon-wise, and raised from its bed, from which oozed a very fœtid purulent discharge. The skin in the immediate neighbourhood was ulcerating. The other nails showed changes such as may be seen in the drawing. Some were ridged transversely, and discoloured at the distal portions; others were stunted and misshapen, evidently new nails; some were separated from their beds half way towards the fold. A piece of paper could be slipped beneath them, showing that there was no massing of epidermis between the nail and its bed. The separated portion of the nail was blackened with dirt, but its texture was unaltered. The toe-nails had been stunted and misshapen for some time; none had suppurated. The mother's statement was, that the finger-nails presented no unusual appearance until twelve months ago, when certain of those on the right hand gradually turned black (presumably by separation from their beds and discolouration). When the blackened portion reached the fold, the finger-ends festered, and the nails were shed. Some of the nails of the left hand, not corresponding with those affected on the right, underwent similar changes. There were no signs of syphilis in the patient or other members of the family (father not seen); no history of dartrous affection (psoriasis, eczema, &c.); no traumatic cause for the disease was discoverable; no fungus found; appearances were in favour of the correctness of the mother's statement. The disease seemed to consist essentially in a separation of the nail from its bed; the onychia condition being possibly due to accumulated dirt, most probably in some instances to the contagion of pus.

No discussion on this paper taking place,

Mr. MORRIS exhibited a patient, whose case is described in the tenth volume of the Clinical Society's Transactions, from whom he removed a large myeloid tumour of the radius by excising that bone from the wrist to the insertion of the supinator brevis, together with the lower four inches of the ulna. He brought her under the notice of the Society as an encouragement to surgeons to excise rather than amputate for such growth of the bones of the upper extremity. It was now four years since the operation, and yet there was no sign of recurrence of the disease. The degree of usefulness of the hand thus preserved to the patient was very considerable. By the aid of a simple leather splint she was able to nurse, dress, and wash her children, do all her household work, wash linen, and carve her own and her children's food. She could also stitch and darn, and was able to take up a pin from off a table between her index and middle fingers, and pin her shawl together. Without her splint, since the contraction of the soft tissues between the hand and the end of the bones of the forearm had taken place, she was able without support to hold her hand out straight from the elbow. Mr. Morris remarked that before the operation he determined to remove a considerable part of the ulna, so as to avoid the great and permanent abduction which must have resulted if the lower end of that bone had been left untouched; and that at the time of the operation he found that, owing to the firm adhesions between the tumour and the outer side of the ulna, he would have been obliged to remove the lower part of that bone if he had not so predetermined. His only regret now was that he had not taken away as much of the ulna as of the radius, for the retraction of the hand had been so great that the lower end of the remaining ulna slightly overlapped the back of the carpus, and gave rise to some friction between the splint and the skin covering the bone, almost to the extent of forming a subcutaneous bursa. Indeed, for a time he thought a bursa had been formed, but this appearance had subsided of late. It would be admitted, he was sure, by any surgeon who examined the limb, that so far from being useless or an encumbrance, it was a very useful and serviceable member, and such was the conviction of the patient herself.

Mr. CHRISTOPHER HEATH on

### TWO CASES OF POPLITEAL ANEURISM CURED BY ESMARCH'S BANDAGE.

The first patient was a coal-miner, æt. 32, with a small popliteal aneurism. Flexion of the knee having been tried without effect, Esmarch's elastic bandage was applied below the knee, and an elastic bandage and cord above the knee, so that the sac was kept tense with blood and pulseless. This was borne for one hour without anæsthetics, and for two hours under the influence of bichloride of ethylene, and at the end of the three hours the sac had become solidified. The patient had been exhibited to the Society at a previous meeting, and had now gone home to Wales. The second patient was a potman, æt. 37, with a small popliteal aneurism, presumably tubular. Esmarch's bandage was applied above and below the knee, but it was noted that though pulsation was arrested, the sac was not rendered as tense as in the former case. On removal after three hours pulsation returned as strongly as before. Digital compression of the femoral was then maintained for three hours with marked effect, but without curing the aneurism. A second application of Esmarch's bandage rendering the sac tense, and producing local ecchymosis, was successful in stopping the pulsation permanently. Mr. Heath laid stress upon the importance of putting no pressure upon the aneurism itself, and of keeping it tense with blood in order to induce coagulation of the contents of the sac.

Mr. SYDNEY JONES said the cases were remarkably interesting, in showing that a limb may be submitted to compression for a lengthened period without impairment of nutrition. He had employed Esmarch's bandage in one case of axillary aneurism, and in two others of popliteal aneurism. In the latter he kept the bandage on for one hour only, resorting then to digital compression. In the second case he was driven to reapply the bandage after some continuance of digital compression. He put on the bandage, tightly from below up, but left it loosely applied over the aneurism, and then tightening again above, completed by adjusting the elastic ligature in this situation. He could not agree entirely that distension of the sac facilitates clotting within it, and believed that the contraction of the sac was an important part of the process. The remedial measures which favour distension of the sac interfere with its vitality. In Hunter's operation the tying of the artery brings about contraction of the sac.

Mr. HULKE thought that there might be danger of rupturing the sac if it became too greatly distended. It could not be foretold to what extent any sac might be distended with safety.

Mr. HOWARD MARSH wished to know the reason why the bandage was removed last of all.

Mr. JOHN CROFT said he had reported a case of aneurism cured by the use of Esmarch's bandage in January, 1878. It was the first in which he adopted this plan of treatment, and the result was very successful, cure occurring within six hours. The bandage had been employed for one hour only, and at the end of six hours the aneurism was a solid tumour. In another more recent case, that of a man 36 years old, syphilitic history, a tumour size of a small orange had been noticed for ten weeks. Being treated on a similar plan, the bandage was applied for one hour. At the end of this time, the tourniquet (used in place of the elastic cord, above the aneurism) being removed, pulsation returned, but to a much less extent than was apparent before. Digital compression maintained for two and a-half hours sufficed to produce a solid tumour, the whole time occupied in securing this good result being thus three hours and a-half. He (Mr. Croft) had carefully watched the reports of cases, and was much interested in the records of time occupied by operation. He thought it unwise to submit the patient to a lengthened application of the bandage, or to long continued anæsthesia, as these could not fail to exert an injurious influence, the latter especially as being likely to retard coagulation of blood. It was not absolutely necessary to cure that complete coagulation should occur. It was essential only that this should be sufficient in extent to promote the after and total solidification of the sac's contents. He wished to know if Mr. Heath had come to any conclusion, as to the influence on the course of the treatment, of bichloride of ethylene, and ether respectively.

Mr. **Thos. Smith** said Mr. Sydney Jones had shown that no harm was done to the nutrition of a limb submitted to continuous pressure for one or two hours. He thought the use of the elastic cord, tied over the bandage to protect the limb, an improvement on the use of the Italian tourniquet. He remembered two cases of paralysis consequent on the non-observance of the precaution. He noticed that the clot following the use of Esmarch's bandage is not always permanent. On three occasions a seemingly firm coagulum had disappeared, and necessitated ligature of the vessel. In another the coagulum vanished, and left the patient in a condition similar to that he was in before treatment. He did not think it was possible to allot an average time, and agreed with Mr. Heath that the tensing of the sac is the correct plan to follow. In his own experience, patients said to have been cured have been compelled to reapply for treatment. Referring to anæsthetics, Mr. Smith related the history of a case, that of a medical gentleman, in whom a popliteal aneurism was cured with the aid of no other pain-killer than an evening paper. The time occupied in treatment was three hours.

Mr. **Hulke** remarked, in connection with the question of the non-interference with nutrition, even under continued compression, that skin grafts in great numbers succeed, even when taken from corpses as long as four hours dead.

Dr. **Mahomed** suggested that coagulation of the contents of the aneurismal sac might be hastened by puncturing the distended wall with a galvanic needle. He thought the introduction of this plan might lead to valuable hints for treatment of thoracic aneurism; also, he suggested, a weak solution of tinct. ferri perchlor. injected into the sac might facilitate clotting,

Mr. **Morrant Baker** had had one case of cured aneurism by means of the bandage which had been applied for one hour, and followed by digital compression for one hour; then again Esmarch's bandage was put on for half-an-hour, and subsequent digital compression resorted to for four or five hours. No anæsthetic was employed, and a solid tumour resulted, and remained. He would like to hear what special advantages were possessed by bichloride of methylene.

Mr. **Smith** said he had been unable to use any sufficien force in compressing the artery of the patient he referred tt until the latter was provided with a pipe of tobacco. Ho then supported the treatment well, and the pulsations, hitherto uncontrollable, were entirely overcome.

Mr. **Croft** said that in neither of his cases was any anæsthetic used beyond one-third grain of morphia.

Mr. **Heath** wished to correct an error into which several speakers had fallen. The anæsthetic he employed was bichloride of ethylene, not methylene, which is far too dangerous an agent for the purpose. He did not believe that its employment retarded coagulation It had been asserted by the Dublin school of surgeons that the pain in the sac, at the moment of cure, is extreme, and in order to enable the patient to bear this, and thereby preventing interference with the plan of treatment, he was favourable to the use of anæsthetics. Both his cases had been small, thick-walled tumours, and one distinctly tubular. No danger, therefore, was to be feared from distension, but he quite thought a large, thin-walled sac would be a dangerous subject to treat so. His second case was the more interesting one. It was not cured at the first attempt, because the sac was not tensed. This plan of cure is diametrically opposed to the ligation treatment, during which the sac is emptied for a time. The collateral circulation then gradually fills it, and successive layers of fibrin are deposited. Broca condemned the coagulation of a passive clot, as leading to suppuration, an opinion falsified by clinical experience. He (Mr. Heath) was convinced the sac must be made as full as possible and kept so. The time is a purely empirical matter. He thought the limb might be kept even longer than any term named under compression, with no evil consequence following. A case had been recorded last year in which gangrene succeeded treatment, but in it there had been extensive vascular disease also. In reply to Mr. Howard Marsh, Mr. Heath said he removed the tourniquet first, purely for convenience, it being advisable not to disturb anything beyond the sac till the latest possible moment. With respect to the proposal to puncture the sac, he would be loth to resort to any such plan, but in any case he would leave the needle in the sac, and not extract it again at the risk of reducing its tension.

"SALUS POPULI SUPREMA LEX.'

WEDNESDAY, FEBRUARY 18, 1880.

## THE ELECTIVE RIGHTS OF FELLOWS IN REGARD TO THE GENERAL MEDICAL COUNCIL.

In the special general meeting of the Royal College of Surgeons in Ireland, which was held on Saturday last, "to deliberate and consult about the election of a representative of the College in the General Medical Council," a question was for the first time formally raised second in interest and importance to none of those issues which, in connection with the reconstruction of the General Medical Council, now agitate the profession. Our issue of last week informed our readers that the Fellows of the Irish College had availed themselves of their chartered prerogative to call the College together to debate this subject, and in the *Medical Press and Circular* for Feb. 4 we discussed generally the legal and moral rights of

Fellows to choose their own representative, maintaining that the assumption of the elective prerogative by an Executive Council was a clear violation of both the intent and the letter of the Medical Act. This view of the law, and of the rights of the Fellows, had been put forward some weeks ago in the Council of the Irish College by Dr. Jacob, and a resolution moved by him that, before proceeding to the re-election of Mr. MacNamara as representative, legal advice should be taken as to the validity of the Council's electoral act. That resolution was not seconded, and in appealing to the judgment of the Fellows at large, it devolved upon Dr. Jacob to lay before them his interpretation of the Medical Act, and of the College Charters and Bye-laws, and to submit a *prima facie* case for further inquiry. The following resolution was therefore moved by him, and seconded by Dr. Robert MacDonnell:—

"That, in the opinion of the College, it is desirable that any doubt which may exist respecting the right of election of the representative of this College in the General Medical Council should be removed; and the College, therefore, recommends to the Council to take, without avoidable delay, the best legal advice as to the rights of the Fellows in such election.

"That the Council be requested to report to the College, as soon as convenient, whatever action it may adopt upon this recommendation, and to submit with such report copies of any case which may be laid before Council, and of the legal opinion thereon."

It is worth while to follow briefly the line of argument offered by Dr. Jacob, and based upon the terms of the Charters and Bye-laws of the College itself.

On the 2nd of August, 1858, the Medical Act became law. The only words in that Act which determine the point raised are (sec. 4)—"The General Medical Council shall consist of one person chosen from time to time by each of the following bodies"—amongst others, the Irish College of Surgeons—and (sec. 6), "the Members chosen by the medical corporations, &c., &c., shall be the Branch Councils." In no part of the Act, nor in any part of the seven Medical Bills which preceded it, is an election by an Executive Council referred to, but, on the contrary, the words "body" and "corporation" are always used to define the elective tribunal. Thus it is plain that the moot point resolves itself into the question, what is, in each particular licensing institution, the "Body?" In the case of some Universities the "Body" is the Convocation, a mixed assembly of clergymen, barristers, and other professional men, with a small leaven of medical men therein. In other cases the Body is a senate partly nominated by the Crown, partly elected by the graduates. In other cases the Body is a small number of privileged medical voters. In the case of the London and Dublin Colleges of Surgeons, the question arises whether the Executive Council is or is not, in point of law, the body corporate.

Confining ourselves to the case of the Irish College, we must, to decide this question, examine the terms of its Charters and Bye-laws. The College is governed by two Charters, granted at 1828 and in 1844, and by such bye-laws as have received the approval of a Secretary of State, and are not repugnant either to public law or to the terms of the Charters. The Charter of 1828 says in the preamble, "And, whereas we are graciously pleased to approve of the said institution and foundation . . . so as to constitute a corporation . . . and further empowering the corporation to create a fund. . . . . Know ye, therefore, that we . . . by these presents . . . do grant A. B. and C., and such others as shall from time to time be elected, to be for ever a body politic and corporate, and which, at all times hereafter . . . shall be called by the name of 'the Royal College of Surgeons in Ireland,' and by the aforesaid name shall . . . to do and execute all other things lawful, necessary, and convenient for the common profit of the said College."

In the preamble of the Charter of 1844, the powers thus given to Members are confined to the Fellows. It says, "and whereas the body politic and corporate of the said College at present consists of persons named and created Members of the said College. . . . And whereas the governing body of the said College consists of the Members of the College. And whereas . . . it appears to us expedient that the several persons who are now Members of the said College should be called Fellows, and that other persons may be appointed or elected Fellows." Know all men, &c.

"1. That all persons who are Members at the date of these presents, together with such persons . . . as shall be elected and admitted, shall be and become Fellows of the said College, and be called or known by the name or style of 'the Fellows of the Royal College of Surgeons in Ireland,' and shall exercise and enjoy all and singular the gifts, grants, liberties, privileges and immunities . . which might be exercised and enjoyed by them as Members for the time being, of the said College, and not hereby altered or amended."

Again, by the following clause, all the powers given to the Members by the Charter of 1828 were continued to the Fellows:—

"And we do hereby further declare our will and pleasure to be that, except in the respects hereby altered, the said College shall continue to have the same jurisdictions, powers, authorities, and discretions, for and with respect to the government of the said College, as such College now has, under or by virtue of the said hereinbefore recited Charter."

Thus it is shown that the Fellows are the "Body" of the College and enjoy all the prerogatives conveyed to the corporation by its Charters. Now, in what do these Privileges consist? and how much of them does the Charter of 1844 relegate to the Council?

The preamble of the Charter of 1844 says:—

"And whereas, it is expedient that . . . . all the powers and privileges of the said body politic and corporate *for the government thereof, and the superintendence and advancement of surgical education and practice*, should be vested in and exercised by an Executive Council of the said College, to be constituted and chosen as hereinafter mentioned."

Again, section 7 says:—

"And it shall be lawful for the Council to exercise their powers and privileges and perform the duties of the said body politic and corporate as to Governing or Executive Council of the said College, and in all respects to act for or on behalf of the said College as lawfully representing the same, and so to make and publish . . . . . such by-laws . . . . as to them shall seem requisite *for the regulation, good government, and advantage* of the said body. . . . . And in case of any emergency to make provision for such emergency, and direct the manner of assembling, electing, or other act or transaction *for the government, discipline, or continuance* of the said body corporate."

It will be deduced from these quotations that the prerogative of the Council is strictly confined to those matters which are conversant with the "regulation and good government," which we interpret to mean the domestic and general administration of the College affairs in which the Fellows have no opportunity of intervening, and we do not find a single word in any Charter or By-law to enlarge the Council prerogative beyond this limit, or to encompass within it the electoral rights inferentially belonging to the Fellows.

The rights possessed by the College and its Council respectively in the election of officers, we find determined by the following clause of the Charter of 1828 :—

"The said President, Vice-President, and Members of the said College lawfully convened may, by the majority of votes of those so convened and assembled, from time to time, elect and appoint a Registrar or Secretary, and elect and appoint such other officer or officers as to them shall seem meet and necessary for the better regulation of said College."

Again, the 11th section of the Charter of 1844 says : "It shall and may be lawful for the . . . . . Council of the said College from time to time to appoint a Secretary (? of the Council), and also to elect and appoint a Registrar and such other officers or servants, for such periods, and at such salaries, as to them may seem meet *for the better regulation of the said College*." And, in pursuance of this power, we find that the College has made bye-laws which provide for the appointment of Secretary of Council, Registrar, Librarian, and Professors, but make no mention of the representative of the College in the General Medical Council.

This is evidence upon which we maintain the right of the Fellows to elect their Medical Council representative, and we are confirmed in our opinion by the well-considered verdict of one of the highest legal authorities in the United Kingdom.

When the first representative of the College was chosen by the Council in 1859 a letter, in the nature of a protest, was addressed to the Council by Dr. Robert MacDonnell, and that letter was strengthened by an opinion given by Lord O'Hagan—then Mr. O'Hagan, Q.C. The question submitted was simply—

"Clause 4 of the 'Medical Practitioners' Bill' provides that 'the General Council shall consist of one person chosen from time to time by each of the following bodies' —among others the Royal College of Surgeons in Ireland. On comparing the clauses of the Charters, do you form the opinion that the right of electing the representative of the College on the General Council belongs to the Council of the College, or should it be exercised by the Fellows ?"

Lord O'Hagan's reply was as follows :—

"The Council has large powers—*all* the powers of the corporation which are necessary for the discharge of its own functions, *i.e.*, for the management and control of the College, the making of its bye-laws, &c., and its general administration. But I do not think that those powers extend any further, or that they are available for a purpose not contemplated by the Charter, and not immediately connected with the government of the College. I do not think that the Council and the College are identical and the same, with perfectly co-extensive privileges under all circumstances ; and it appears to me the better opinion that the Act to which I am referred, in committing a new appointment to a new General Council of Medical Education, which did not exist or was not thought of when the Charter of the College of Surgeons was granted should be held to belong to the College itself, and not to its Council, and that accordingly the right of election should be exercised by the Fellows."

This reply appears to us to be a straightforward answer to a plain question submitted without bias and answered without prejudice. We have heard it said that another and contrary opinion was given by one other eminent lawyer, but, on further inquiry, we learn that that opinion, if it ever existed, was a mere conversational judgment upon a verbal inquiry, and that no one knows either what was the inquiry or what the reply. We are, we think, justified in disregarding such a legal judgment.

We have confined ourselves to a strictly technical statement of the law bearing upon the electoral rights of the Fellows of the Irish College, but we are not to be understood as defending those rights on purely legal grounds, for we contend for the morality, the equity, and the expediency of giving to them the right to choose their own representative, and we maintain our proposition as a matter as much of benefit to the College as of fairness to its constituent members. The College evidently thinks with us, for it has voted the resolution which we have quoted above in a meeting of the College from which the extra-metropolitan members (who are most interested in asserting the right) were almost altogether absent.

The law, when decided by competent advice, may be against our view, but the equity never can be so, and, in any event, we shall feel that somtthing has been gained in the assertion of a principle which, if carried out, will be a valuable aid to General Medical Council Reform.

◆

## THE GARDNER BEQUEST FOR THE BLIND.

Our daily contemporaries have lately devoted considerable space to the consideration of an important question, the Gardner Bequest for the Blind. If this be wasted in bricks and mortar it will, as our facetious friend *Punch* says, lead to a "disorganisation of charity." It is upwards of four years since we forcibly and prominently brought to the notice of our readers and the public the neglected condition of the blind. We then pointed out that asylums are an utter mistake for this class of the afflicted ; for of these we have more than enough and to spare. No greater misapplication of funds could be made than that of founding another palatial building for those amongst our fellow-creatures who, above all others, require to pass their lives with the sighted and in the enjoyment of home associations. To herd them together in asylums is to compel them, for the most part, to lead listless and useless lives. The directors of the old asylums have long ago discovered this, and would gladly see their asylums applied to a better purpose. The aggregation of the blind, equally with other classes, is quite as certain to lead to the deterioration of the health of mind and body, and become a focus for infectious diseases. Why, then, perpetuate the folly and vanity of charity-mongers, and found an asylum where the least deserving of the blind shall be lodged in idleness?

The chief problem to be solved in respect of the blind is how best to render them useful members of society. It is perfectly certain that the blind, when properly educated, can compete successfully with the seeing. The contention that has long been going on with reference as to which is the best type for the learner is of little consequence, as Mr. Fawcett, Dr. Armitage, and other successful blind men, so usefully engaged in various walks of life, invariably assert. There is, however, a greater difficulty with regard to the blind, both young and old, it is that of getting them taught thoroughly what they have to learn, at the best age and by the most scientific methods; this, again, is a difficulty which, under the School Board of London, is fast vanishing. There are in the United Kingdom about 30,000 blind, the majority of whom are to be found in the agricultural and mining districts. Parents very naturally refuse to part with their afflicted children, and consequently asylums are shunned. The voting system adopted by charitable institutions makes it difficult to act at the best time and to the greatest advantage in the educational training of the child. But where this is not the case there seems to be considerable objection to the asylum system. The schools do not fill for the reason we have intimated, as seen in Sheffield, where in September last a new school was opened for both sexes, capable of affording accommodation for 100 pupils, and at present not half the number have as yet been brought in. The several London asylums are almost exclusively occupied by a class (the pauper class) already well provided for by the Poor-law of 1870. The School Board of London, assisted by the Rev. Mr. Stainer, is now making a further effort to deal with all classes of the blind, inclusive of the well-to-do classes, all or any of whom are received into these schools, where they will obtain the best possible education. The School Board Visitors of London had some months ago found 183 blind children, and they hoped soon to bring all the blind children of the metropolis into their schools, and at the very trifling cost to the parents of the majority of 2d. per week. There can be no question, then, that if all those persons who feel interested in the education of the blind were to act in concert, and help in carrying out the provisions of the Legislature,(a) the whole question of the education, up to the age of fourteen, would be amply cared for, and that charitable funds, so far as children are concerned, would be set free to further the education of the more promising amongst the pupils of the School Board, provide scholarships, and continue their education at the normal college at Norwood or Worcester. As to the adult blind, it is now generally admitted that they, as well as children, should be taught to live and work with the sighted; that they should not be placed in institutions or asylums, but taught in workshops, and helped to live in their own families and neighbourhood. The great want of the blind is the establishment of a sufficient number of these workshops throughout the country. We are assured by the secretary of the Sheffield Institution that the workshops there have for six years been entirely self-supporting. At present, in the few workshops in London, with the aid of all the charities there are only 127 blind employed out of about 900 able and willing to contribute towards their own support. It is therefore perfectly clear that the Gardner bequest could not be better employed than in founding workshops and educating the better classes in science and other ways, and in founding pensions for poor and deserving blind persons, or such like purposes, throughout the country.

◆

# Notes on Current Topics.

## Dr. Farr and the Government.

A DEFINITE explanation of the reason why Dr. Farr has been superseded in the appointment of the new Registrar-General has been at length vouchsafed by the author of the "job." The Prime Minister, in reply to Lord Lothian's request on Friday evening, described the details which preceded the election of Sir Brydges Henniker. The precarious health and advanced age of Dr. Farr are declared to have been an insuperable bar to his appointment, "particularly at this moment when preparations are being made for taking a new census of the country." Lord Beaconsfield also entered on a somewhat laboured description of the many facts which appeared to him to warrant the removal of one thoroughly familiar with the intimate working of the office, in order that a younger and entirely untried man might be set therein, "because, on the whole, the Premier believed him most competent to fulfil its duties." As the noble Lord then somewhat inconsistently avowed that "he (Sir Brydges Henniker) was an individual with whom he had no personal acquaintance," it would be interesting to learn on what the conclusion as to the special fitness of an unknown nominee is based. Construed in the most liberal spirit possible, it cannot be said that the explanation of the appointment is either satisfactory to the public, or calculated to add anything to the reputation of the Government for discrimination in questions of patronage. Lord Beaconsfield, however, did well to contradict the silly rumour current in certain quarters, that Dr. Farr's medical qualifications were the reason of his non-election. The idea is so transparently absurd that it had been hardly worthy of attention but for the fact of some usually well-informed papers having given prominence to it.

## Toxic Effects of Tea.

DR. C. L. DANA contributes an interesting paper to the *New York Medical Record*, Jan. 24, on the subject of the influence exerted on tea-tasters by the drug. The conclusions he arrives at are at variance with those usually received. He finds that no evil consequences follow prolonged tea-tasting; and records the histories of ten cases in which the trade had been pursued for periods of from thirty to forty years. In every instance the health was unimpaired, sight good, and likewise digestion. In one case dyspepsia had been cured by the tea-tasting. It is noticeable that tobacco was universally used by the gentlemen examined; but its effect on the taste was a subject of dispute. In reconciling these results with the generally received opinions as to the poisonous nature of tea, Dr. Dana announces that a very small quantity of the *thein* is absorbed into the system, the practice of spitting out the greater quantity of tea tasted preventing much from being taken up. He found, too, that provided this precaution is observed at once, commencing tea-tasters are as little affected as the veteran hands. Dr. Dana considers that Dr. Wolfe's theory that tea-drinking is productive of injury to the eye-ball is not based on fact. Dr. Wolfe, in a paper read before the British Medical Association last summer described injury to the vitreous humour following the use of tea. Dr. Dana could not obtain any confirmation of these observations, during his inquiries.

---

(a) An excellent analysis of the Acts bearing on the question of the Blind can be had at the *Newsvendor* office, 15 Russell Street, Covent Garden.

## "Time" on "Our Doctors."

UNDER the pseudonym of Dr. Andrew Spark, the Senior Physician to the London Hospital is described in the February number of *Time.* No less happy when discussing the peculiarities of Dr. Andrew Clark than with the other subjects of his pen, the essayist has reproduced the mannerisms which characterise the speech of the popular physician, and has drawn a picture of him which will be recognised as a most faithful portrait by all to whom he is familiar. The incisive utterances of Dr. Clark have often fallen on the ear of the student with a force that has been productive of the best results in stimulating to a desire for further knowledge. And no less convincing, we may take it, is he when his aim is to convert a patient to a sense of error, and to instil a wish for amendment by emphasising his lesson with the assertion that "Nature is implacable." The tone of this essay, however, is somewhat destructive of the impression left by the earlier ones. These had the appearance of being written by an appreciative lay person, but the sketch of Dr. Andrew Spark is highly suggestive of a professional pen. We should be sorry to know that our first opinion was wrong, and that the bright little series of articles is, after all, written with a purpose other than that of showing that such a subject can be made interesting, and to prove how the general public can accord an honest praise to worth. We are led to this doubting condition of mind the more because we were for a long time puzzled to recognise the original of Mr. Osric Claypole, until the somewhat fulsome description of his practice enabled us to associate him with Mr. Clayton, a surgeon less known in the literary world of medicine, than in the more pleasure-seeking section of the profession. The sketch is probably a good one; it is undoubtedly the most "racy", of the series yet issued; there may be a fear, however, that the continuation of the series may be something more objectionable if simple merit ceases to be the author's standard of worth.

## The Dover Hospital.

A RULE providing that the house surgeon to the Dover Hospital should not practise in the town was recently rescinded, and, as a consequence, the medical staff of the institution resigned bodily. The difficulty has now been arranged at a meeting of the governors, who have voted "by a large majority," that, until he has served for a period of five years, the resident surgeon shall not be entitled to enter on private practice in Dover. It seems to us that the importance attached to this question is somewhat greater than it deserves. The staff of the hospital should surely be in a position to look carelessly on the pretensions of a stranger who entered into competition with them in Dover. The extremely jealous manner in which they have sought to preserve the status they have attained to, is suggestive to outsiders of an unwillingness to endanger their position by exercising a liberal spirit of welcome, to everyone willing to encounter them in the race for practice. The facilities of acquiring introductions to patients from the Dover Hospital may be unusually great, but, even so, the tried excellence of a resident practitioner should preserve him from injury by a new aspirant. From all points of view the action of the staff of the Dover Hospital is unsatisfactory, and but ill accords with the dignity of an influential body.

## The Appointment of the Queen's Medical Advisers in Ireland.

WE have referred in our last two issues to the pending selection of a Physician to the Queen in Ireland, in place of Sir Dominic Corrigan. The occasion makes it appropriate for us to discuss the method of that selection, and to deprecate on behalf of the profession in Ireland the happy-go-lucky system by which a choice is made of the person to receive such a distinction. It must be recollected that the office of Physician to the Queen in Ireland is purely an honorary distinction, and that into the selection of an occupant her Majesty's personal feeling does not enter at all. In England or Scotland it would be quite reasonable that the Queen, as a matter of individual choice, might select a physician who was held in less estimation by the profession and the public than other competitors for the honour, but in more regard by her Majesty, and we could not therefore well complain if—as has been done before now—a physician of lower scientific grade were distinguished by her Majesty's choice. In Ireland the case is quite different, for—calculating from past experience—it is immeasurably improbable that her Majesty will ever see her physician. In Ireland, therefore, we submit that the physiciancy or surgeoncy to the Queen is as much a nominal and honorary distinction as is the order of knighthood, and that it ought to be conferred, in all fairness, upon the man who is declared by professional acclamation to be upon the whole the most deserving physician or the most original and skilful surgeon. In this view of the matter we warmly deprecate the interference of politics in the selection, and we are glad to know that, as a matter of fact, political influences do not exercise much—if any—control over her Majesty's choice. But then it is our complaint that, so far as we know, no effectual means are adopted of informing the Queen as to the relative claims of those who might deserve the honour, and consequently the selection might nearly as well be made by a throw of the dice. If we are rightly advised, the question is usually decided upon the *ipse dixit* of one or other of the London Court physicians, who probably has as little personal knowledge as to the relative merits of Dublin surgeons, physicians, dentists, or ophthalmologists, as of Dublin solicitors or popular preachers. It is as if one of her Majesty's London chaplains were asked to advise the appointment of a Bishop of Killaloe, and his recommendation be accepted as final.

We urge, therefore, that it is very unfair to the profession in Ireland, and derogates very much from the honour of being named her Majesty's professional adviser, that that nomination should be made upon the mental bias of any one person, or of any number of uninformed persons. We certainly think that her Majesty's physicians have an implied function to advise her Majesty as to who is the physician most deserving of her gracious notice, and that a similar view should be acted upon in the nomination of surgeons or ophthalmologists to her Majesty, and we respectfully submit this aspect of the matter to the consideration of the Lord Chamberlain.

### Exchanges of Army Surgeons.

A General Order under date of the 1st of the present month has been issued by the Horse Guards, which provides that exchanges between officers of the Army Medical Department at home and foreign stations will be permitted to the same extent as in the case of combatant officers, under the qualifying conditions as to promotion specified in Articles 15, 18, and 21 of the Royal Warrant for the Department of November 27, 1879. But, except under special circumstances, exchanges between medical officers serving in the United Kingdom will not be permitted unless the officers have been at least two years at their respective stations.

Deputy Surgeon-Gen. Edward Gilborne has been gazetted to the rank of Surgeon-General, and appointed Principal Medical Officer on military service in Ireland.

In order to prevent the introduction of *phylloxera* into Turkey, the government of that country has just issued an order interdicting the importation of trees and plants.

Surgeon-Gen. C. A. Gordon, M.D., C.B., a frequent contributor to our pages, who is at present home from India, has been for the second time appointed Principal Medical Officer of the Southern Military District.

A large block of tenements has just been demolished in Bedfordbury, the site has been taken for the new medical school attached to Charing Cross Hospital. The number of students having increased beyond its present accommodation has necessitated this step.

It is understood, says the *Broad Arrow*, that the Naval Medical Service is to be rendered more attractive than it has hitherto proved itself, and that a warrant placing it in point of pay, &c., on a similar footing to the Army Medical Department will shortly be issued.

At a meeting of the Metropolitan Board of Works on Friday last, it was agreed on the recommendation of the finance committee to lend the guardians of St. Marylebone a sum of £27,500 for the completion of their new infirmary at Notting Hill.

The authorities of the city of Winchester are determined to make it a model of sanitation. The enormous sum of £32,000 has already been expended upon drainage, and the Town Council of Winchester have now applied for sanction to contract a loan of £4,500, required to complete the scheme.

We regret to announce the death of one of the few members of the profession in the House of Commons, in the person of Dr. O'Leary, M.P. for Drogheda, which occurred in London on Saturday last from congestion of the lungs, after three days' illness. Dr. O'Leary was surgeon to St. Vincent's Hospital, Dublin, and had only attained the age of 41.

At an adjourned inquest held on Saturday last, on the body of a patient who died in the Bicton Public Asylum under suspicious circumstances, the jury returned a verdict "That death resulted from congestion of the brain and bronchitis, accelerated by fractures of the breast bone and ribs, but how such fractures happened there was no evidence to show."

The names of twenty-nine ladies appear in the list of candidates who passed the matriculation examination at the London University, in January. Two of them are in the Honours Division, and one of these is at the top of the list, but is disqualified by age for the first exhibition. Seventeen ladies passed in the first division, and five in the second division.

Last week the highest rate of mortality in the United Kingdom was reached in London. The rate, 48 per 1,000 of its population is without parallel, except during the cholera epidemic, and showed the disastrous effects of persistent dense fogs upon the respiratory organs, especially of elderly people; the excessive mortality being chiefly confined to those above sixty years of age.

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Wolverhampton 16, Birmingham 21, Newcastle-upon-Tyne 21, Sheffield 22, Oldham 22, Leicester 22, Edinburgh 22, Brighton 23, Bradford 25, Glasgow 25, Portsmouth 26, Plymouth 26, Salford 27, Leeds 27, Liverpool 28, Sunderland 29, Bristol 30, Norwich 30, Manchester 32, Nottingham 32, Hull 32, Dublin 43, and the highest rate 48 in London.

A poor silly cad, lately arrested in Dublin for knocker-wrenching, gave his name as Thomas Kennedy, medical student of Trinity College. The Registrar of the school of the University has written to the magistrate and to the newspapers to state, on the authority of the matriculation books, that the description of the delinquent is a falsehood, and that no medical student of the name given is on the books.

---

Dr. A. Mussen, medical officer for the Glenavy Dispensary District of the Lisburn Union, has been elected coroner for the Belfast district, co. Antrim.

---

From the Register of the Pharmaceutical Society of England we learn that the number of pharmaceutical chemists in England at the 31st of December last was 2,299, and of registered chemists and druggists 11,252, giving a total of 13,551.

---

At the Annual Meeting of the Governors of St. Mark's Hospital for Fistula, held at the Mansion House on Thursday, the 12th inst., under the presidency of the Right Hon. the Lord Mayor, Dr. Frs. de Havilland Hall was unanimously elected as hon. physician to the hospital, in the room of the late Dr. Leared.

---

On Friday last, a deputation from the Parliamentary Bills Committee of the British Medical Association waited on the Home Secretary anent the Coroners Bill. It was pointed out that within the last 40 years various failures had occurred in the administration of justice, especially in poisoning cases, owing to the want of scientific and medical knowledge on the part of coroners. Mr. Cross informed the deputation that the Bill, as drafted by himself, provided for these deficiencies.

---

In the principal foreign cities the rates of mortality, according to the most recent weekly official returns, were—in Calcutta 34, Bombay 35, Madras 40; Paris 42; Geneva 34; Brussels 32; Amsterdam 37, Rotterdam 28, The Hague 30; Copenhagen 23; Stockholm 19; Christiania 12; St. Petersburgh 48; Berlin 26, Hamburg 31, Dresden 23, Breslau 25, Munich 34; Vienna 29; Rome 48, Naples 35, Turin 49, Venice 49; Alexandria 35; and NewYork 26, per 1,000 of the populations. Typhoid fever caused 101, and small-pox 72 deaths in Paris.

---

An epidemic on a small scale is at present raging in Paris; typhoid and small-pox being the principal zymotics. From the former no fewer than 101 persons succumbed last week, and 72 from the latter, figures which are not a little alarming. Paris has at present a death-rate of 42 per 1,000, the rise being attributable in some measure to dense fogs as in London. But whilst the latter city has already reverted to its normal death-rate with the advent of bright weather, the former has an excessive mortality from typhoid and small-pox.

---

Last week the death-rate in the nineteen provincial towns did not average more than 26·3 per 1,000, against 48·1 in the Metropolis. The annual death-rate from the seven principal zymotic diseases ranged from 0·7 and 0·8 in Wolverhampton and Portsmouth, to 6·3, 6·8, and 7·0 in Sunderland, Dublin, and Hull. Whooping-cough caused no less than 248 deaths in London. Small-pox caused 14 more deaths in London and in its Outer Ring of suburban districts, 8 in Dublin, but none in the other large towns. Deaths from affections of the respiratory organs rose to the extraordinary total of 1,557, the highest rate on record.

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**The Mortality in Glasgow.**—The deaths in Glasgow for the week ending with Saturday, the 7th inst., were at the rate of 25 per 1,000 per annum, against 26 in the preceding week, and 27, 30, and 27 in the corresponding weeks of 1879, 1878, and 1877.

**Health of Edinburgh.**—For the week ending with Saturday, the 7th inst., the mortality in Edinburgh was 95 and the death-rate 23 per 1,000. Only one death from fever was recorded, and that was in the Old Town. There were four from scarlatina, three of which occurred in the New Town and one in the Old. Of 144 births, 11 were illegitimate.

**Govan Death-Rate.**—The report of the medical officer of health for the burgh of Govan for the past month was presented to the Commissioners of Police on the 9th inst. It showed that the health of the burgh was satisfactory. There were 80 deaths during the past month, being at the rate of 20·42 per 1,000 of the estimated population.

**Mortality in Partick.**—The report of Dr. Patterson, the medical officer of Partick, presented to the Commissioners of Police on the 9th inst., stated that during the month of January the health of the burgh had been fairly good, although measles still existed. The deaths registered were 46, giving a ratio of 19·85 per 1,000 of the population. Of the deaths, 20 were of children under five years of age, 9 of infants under one year, and 8 of persons above 60.

**A Healthy Town.**—The vital statistics for the burgh of Dunfermline for the latter six months of 1879 have just been issued by the medical officer of health, Dr. Morris. The births numbered 400 and the deaths 194, the death-rate being thus 16 per 1,000 per annum, and the birth-rate 34½.

**Registrar-General's Monthly Return.**—According to the monthly return of the Registrar-General, there were registered in the eight principal towns of Scotland during the month of January, 1880, the births of 3,681 children, of whom 1,908 were males and 1,773 females. Of these 3,391 were legitimate, being in the proportion of 1 illegitimate in every 12·7 births, or the illegitimate births constituted 7·9 per cent. of the whole. The deaths of 2,594 persons were registered in the eight principal towns during the month, of whom 1,310 were males and 1,284 females. Increase of population being allowed for, the number is 616 under the average of the corresponding month of the last ten years. A comparison of the deaths registered in the eight towns shows that during January the mortality was at the annual rate of 20 deaths per 1,000 in Greenock, 21 in Perth, 22 in Edinburgh and in Leith, 25 in Glasgow and in Aberdeen, 26 in Dundee, and 36 in Paisley. In the case of Paisley there is reason for believing that the death-rate above stated is too high, for the existing population is thought to exceed the estimate by about 5,000. Of the 2,594 deaths, 1,078, or 42 per cent., were of children under five years of age. In Perth 26 per cent. of the persons who died were under five years of age, in Edinburgh 37, in Paisley 38, in Aberdeen 39, in Greenock 40, in Dundee and in Leith 42, and in Glasgow 44 per cent. The miasmatic order of the zymotic (epidemic and contagious) class of diseases proved fatal to 328 persons, constituting 12·6 per cent. of the whole mortality. Hooping-cough continues to be the most fatal epidemic, having caused 135 deaths, or 5·2 per cent. of the whole. In Glasgow 7·2, and in Aberdeen 7·5, per cent. of the deaths arose from this cause. Scarlatina caused 52 deaths, croup 28, diarrhœa 26, diphtheria 18, and metria 7. Ninety-nine deaths resulted from violent causes, of which 31 were occasioned by the accident at the Tay Bridge on the 28th December, and five were suicides. Four deaths were caused by delirium tremens, and eleven by the direct effects of intemperance. One male and seven females had passed the ninetieth year of life, the eldest of whom was ninety-seven years.

LEITH HOSPITAL.—The annual meeting of the subscribers to the Leith Hospital was held on the 9th inst., in the Trinity House, Kirkgate, Provost Henderson presiding. The annual report was read by Mr. Mann, secretary. It stated that the total number of patients treated in the hospital during the year was 380. Of these 281 had been cured, 46 relieved, 40 died, and 13 remained in hospital. Seventy-five cases had been treated in the fever department; 155 in the casualty department; submersions, 6; general disease, 144. The total number of admissions to the hospital considerably exceeded that of the previous year. The dispensary department had also largely been taken advantage of. During the year 4,092 patients had been prescribed for. The deaths averaged one in ten cases. For the year the income had amounted to £2,046, and the expenditure to £2,016 16s. 6d. Several of the new wards were still closed owing to the want of income to maintain them. The directors thought that out of a population of 50,000 it was not too much to ask that the subscriptions should be increased to about £1,500 a year, instead of £700, as during the past year. They appealed to the public to increase their annual subscriptions. A vote of thanks was given to the medical officers for their gratuitous services during the past year. The office-bearers for the ensuing year were then appointed.

JOHNSTONE.—INFECTIOUS DISEASES HOSPITAL.—On the 12th inst. a meeting of the representatives from the Johnstone Local Authority and the Abbey Parochial Board was held for the purpose of considering the hospital accommodation for infectious diseases. After a long and animated discussion it was resolved to appoint a committee of four to look out for a suitable site and report.

◆

# Literature.

## LECTURES ON BRIGHT'S DISEASE OF THE KIDNEYS. (a)

DISEASES of the kidney have long possessed a special charm for the scientific physician, due doubtless in a large measure to the delicate and complicated structure of the organ, the interesting physiological processes of which it is the seat, and the serious and extensive pathological sequences which its diseased condition entails. The work before us consists of lectures delivered at the School of Medicine of Paris by Professor Charcot, a gentlemen well known to readers of French medical literature as pre-eminently distinguished by his devotedness to pathological research, and the translation into English is by Dr. H. B. Millard, of New York. The lectures are limited to a consideration of the normal anatomy of the kidney, its physiological functions, and the pathological changes induced by disease. Lecture I. treats of the normal anatomy of the kidney, and embraces all the most recent discoveries. A clear description of the "loops of Henle" is given, a correct knowledge of which is so important as bearing on the significance of tube casts. Consideration of the convoluted tubes is then entered upon, and the peculiarities of the epithelium in the whole tubal system minutely and succintly contrasted. Lecture II. continues "the normal anatomy of the kidney," embracing a description of the connective tissue of the kidney, and discussing the contradictory opinions of various authors regarding it, treats of the lymphatic and other vessels of the kidney, and the seat of the urinary secretion, in the light of the most recent investigations, and notably those of Heidenham. As into other organs of the body, certain conditions may determine into the kidney—effusion of blood or of one or more of its constituents — so accordingly we have then to deal with the various forms of *infarctus* described in Lecture III. The clinical significance of tube casts is one with which the student ought to be thoroughly conversant, that he may be spared the reproach of frequent hasty and erroneous diagnosis, and on this point Charcot is at once instructive, concise, and reliable. Regarding the *unity* or *duality* of Bright's disease in its initial stages, our author expresses himself as follows:—"You are aware that, in the opinion of the greater part of French or German physicians, the various alterations of the kidney discovered in autopsies of such subjects as during life have suffered from albuminuria and anasarca, correspond to the various successive phases of the same, or to one, morbid process. This opinion represents a doctrine which may be termed *theory of unity* of Bright's disease. According to another doctrine, not of the *duality* but of the *multiplicity* in the forms of Bright's disease, the various forms of renal alteration revealed by the autopsy represent, not the successive phases of the same process, but so many distinct anatomical states, with which are connected during life as many well-characterised symptomatic groups. This doctrine might be called the English theory, since it is especially in England that it has for twenty years been sustained and developed." Charcot professes himself a convert to the latter, or, as he terms it, the English theory. As indicated by Professor Charcot, this theory is one which comes far short of receiving general acceptance; it has been quite recently combated by Rosenstein, it is disbelieved in by many other competent authorities, and it is one opposed, as we believe, to that unity so manifest in nature and disease to the extent that their relations are regarded from the highest scientific standpoint. Reflecting on the highly complex structure of the kidney, the intimate interdependence of the physiological processes concerned, and the fact that the very existence of its interstitial tissue was not long ago disputed by no mean authorities, it is difficult to believe that inflammation and subsequent dependent changes should be so exactly circumscribed and differentiated as certain writers would have us to believe. The whole subject has been made so repellant to the student by the endless variety of arbitrary names employed to designate certain pathological appearances, and by the extreme minutiæ of pathological description, from a practical point of view useless, that the task of unravelling the tangled web is by no means easy, while its extreme desirability is only too palpable. With the aid of these lectures the student will be most materially assisted. At the same time we are disposed to differ from the learned professor in his espousal of the English doctrine. Bright's disease, like cognate diseases in other organs, we believe to be either idiopathic or cachectic; that is to say, primarily due to impressions on the nervous system perverting the normal circulation of healthy blood, which thereby becomes unhealthy, or to the morbid influence on the secretory apparatus of blood rendered impure from various systemic conditions. Between the blood in a state of health and all the secretory organs there is a normal physiological correlation, which may be thus overthrown from two opposite conditions. According to Pflüger the terminal branches of the minute nerve twigs penetrate the walls of the cells, and end even in the nuclei. Depraved blood by irritating these minute twigs destroys their inhibitory power, and hyperæmia results, which, if long enough continued, passes on to morbid change just as idiopathic inflammation from cold, &c., terminates in similar degeneration. Hence it may be accepted as a physiological and pathological axiom that every form of neoplasm has its antecedent hyperæmia, and so far as relates to the kidney we are at one with Rosenstein in his belief that "there is no such thing as nephritis exclusively interstitial, or nephritis exclusively parenchymatous," especially in the earliest stages. To talk of chronic parenchymatous nephritis as being *chronic* from the commencement, as Lecorche does, is to us an unintelligible contradiction in terms. All the pathological varieties (excluding possibly the amyloid changes) appear to us to be capable of being evolved from diffuse inflammation of the kidney.

---

(a) "Lectures on Bright's Disease of the Kidneys." By J. M. Charcot, Professeur à l'Academie de Médecine, Paris. Translated by Henry B. Millard, M.D., A.M. London: Baillière, Tindall, and Cox. 1879.

Charcot's description of the various forms of Bright's disease is singularly clear. He adopts the following simple and commendable classification :—(A.) Parenchymatous nephritis ; (B.) Interstitial nephritis ; and (C.) The amyloid variety. With regard to the cardiac hypertrophy said to result from the renal obstruction, in cases of contracted kidney, Charcot pertinently inquires why, if this be the cause, this effect is not observed in parenchymatous nephritis, in which the embarrassment to the circulation is strongly marked, in consequence of the vessels being compressed in the cervical substance, and theoretical replies are given which are by no means convincing. It is far from clear that this hypertrophy and the renal embarrassment of the circulation stand in the relation of cause and effect, as the absence of this hypertrophy has been long noted in the so-called surgical kidney, often completely stuffed with matter, and its vascular area thus completely destroyed. This fact has quite recently been confirmed by the important observations of Dr. Alfred Jean, of Paris.(*a*) A blood origin of this hypertrophy, which is not simple hypertrophy, is indicated rather by the recent observations of Drs. Debove and Letulle.(*b*) There are many other subjects of importance in Charcot's monograph to which we would willingly direct attention, but from the discussion of which we are necessarily precluded in this place. We would direct the attention of the translator to the fact that the word "macroscopic" is invariably used by him as synonymous with the word "microscopic." We have never heard, for instance, of "macroscopic examination," "macroscopic appearance," &c. So invariably is this word used, that considering the national proclivity in the direction of coining new words, it is quite possible that the word is used advisedly, but there is a vast difference between the adjectives *μακρός* and *μικρός*.

Dr. Millard has laid the profession under obligations to him by this translation. On the whole it is well done, and we doubt very much if there exists in the English language any monograph in which the pathological peculiarities of the various forms of Bright's disease, with their symptoms, are so concisely described. The book ought to prove most acceptable to the student, and we have both confidence and pleasure in heartily recommending it.

## MRS. O'CONNELL'S PAPER ON DELICATE CHILDREN IN WORKHOUSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mrs. O'Connell, of Longfield, recently read a paper before the Statistical Society of Dublin which seems to me to deserve the attention of the medical profession. In it she pleads with a rare eloquence the cause of the sickly and scrofulous children, for whom the workhouse furnishes at present the sole asylum. She paints with wonderful vigour the miserable condition of those poor victims of glandular and allied scrofulous affections whose fate she thinks might be averted by a more genial home than that which the rough jostling with healthier children must needs afford. Mrs. O'Connell's main point, then, is that there exists in workhouses a class of children who without coming under the category of those entitled to treatment in an hospital ward, yet are of so frail a build and have in them the spark of disease so easy to be enkindled that there is need of exceptional institutions for them. Such exceptional treatment she thinks is called for quite as much in the most selfish interest of the ratepayer as in that of the higher requirements of humanity.

With the view taken by this accomplished writer I am entirely disposed to agree. I must say, however, that I do not think some of her facts bear the interpretation she puts on them. Thus she mentions one case of fatal hip disease on which she founds a charge against the existing provisions for hospital treatment. This appears to me to be a fact which tells against the competence of an individual surgeon rather than against the efficiency of the purely hospital department of workhouses. I am myself connected with an extensive workhouse where exceptional provision has long been made for the treatment of this class of children by a very liberal and enlightened board of guardians. I do not think that more care could be taken of them, and yet I do think that there is a percentage of the children, not a very large one indeed, who would stand a better chance of being built up into healthy young men and women in one of Mrs. O'Connell's special institutions than even in the most carefully-tended workhouses.

I am disposed to think that the great city workhouses would supply something more than a small percentage of such children. Much of our workhouse system might indeed be remodelled, but I do not feel called upon to discuss that matter here. Of course if special institutions are to be established everything will depend on the management and not a little on the sites. Nothing would be more easy than to found a system which not only might not be superior to, but might be even inferior to the present one. In conclusion, I cannot help expressing my regret that Mrs. O'Connell's paper has not been published in pamphlet form and sent to the different medical publications for review.

I am, Sir, yours faithfully,

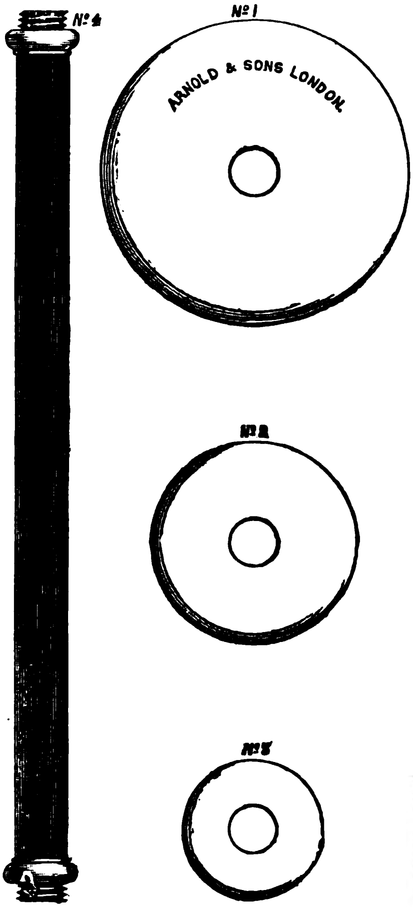
THOMAS LAFFAN.

◆

## NEW MEDICAL OFFICERS' STETHOSCOPE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A great authority on auscultation has remarked that a new stethoscope requires to be tried on as carefully as a new hat. The reason for this is clear. Some men hear best with a concave ear-piece ; others prefer a flat or slightly convex one ; but all seem agreed that the ear-piece, whatever may be its form, is the most important part of a stethoscope. Still the shape and size of the chest-end are not without importance ; for although medical men generally use the same instrument for all cases, pulmonary as well as cardiac, and for all patients, whether lean or stout, it is, nevertheless, a fact, that for the limitation of certain cardiac murmurs, and for the accurate localisation of pulmonary sounds, especially in emaciated patients, a small ended stethoscope is desirable; whilst for collecting faint, distant, or deep-seated pulmonary sounds, a stethoscope with a large chest-end is to be preferred. It would be inconvenient however, to carry two stethoscopes about with us. Even one stethoscope of the usual form is an awkward instrument to carry, and many are the devices that have been adopted to overcome the difficulty. In my early days the stethoscope used frequently to be carried crosswise



---

(*a*) "De la retention incomplete d'urine," &c. Thèse de Paris, 1879.

(*b*) "Note sur les lesions du cœur dans la néphrite interstitielle." Lue à la Société Anatomique, 17th October, 1879.

inside the hat, and many Edinburgh graduates of five-and-twenty years ago will remember the circumstance of a medical student having been accused of being armed with a *life preserver* owing to his stethoscope having rolled out when his hat was knocked off in a snow-balling encounter.

A perfect stethoscope should have the following qualities: It should be portable under all circumstances. It should be a good conductor of sound. Its ear-piece should be of a shape to fit any ear. Its chest-end should be capable of being adapted to any surface, and it should be suitable for any case. The instrument which I have devised will, I believe, meet nearly all these requirements. It consists of four parts—viz., a stem, an ear-piece, and two chest-pieces. The stem is a wooden cylinder, six and a half inches long, having a uniform diameter of half an inch, with a short entering screw at each end. The ear-piece, of boxwood, ivory, or ebony, is slightly convex on one side, and slightly concave on the other, rather less than the eighth of an inch thick, and about two inches in diameter, with a receiving screw in the centre. No. 1 chest-piece exactly resembles the ear-piece, except in having a diameter of only one inch and a half. No. 2 chest-piece is exactly like No. 1, except that it has a diameter of only one inch. The screws of the ear-piece and chest-pieces are all alike, and are made to fit either end of the stem. They are also reversible, so that the surface applied to the ear or to the chest may be either concave or convex as required. Either chest-piece may be used according to the nature of the case. For cardiac cases and very emaciated patients I use the smaller one; but for pulmonary sounds in persons ordinarily well nourished I prefer the larger chest-piece. When the stethoscope is not required for use, the ear and chest-pieces can be unscrewed and carried in the waistcoat pocket, occupying about the same space as a crown, a half-crown, and a shilling; whilst the stem can be carried as easily as a pencil-case. Thus, by substituting a couple of nearly flat chest-pieces for the ordinary trumpet-shaped extremity, an elegant and universally applicable instrument is obtained, which even military medical officers, whose pockets have been reduced to the vanishing point, will be able to find room for. Country doctors also, to whom the ordinary stethoscope is a burden when riding, whether carried in the hat or pocket, would find this instrument particularly useful.

Stethoscopes of this description are now made by Messrs. Arnold & Sons, of West Smithfield, E.C., to whom I am indebted for much intelligent aid in executing my design,

I am, &c.,

## THE VACANT IRISH MEDICAL AND SURGICAL BARONETCIES.

Nothing has yet transpired as to the intentions of Her Majesty regarding the bestowal of the medical baronetcy vacated by the death of Sir Dominic Corrigan and the surgical title which has so long lain unoccupied since the death of Sir Philip Crampton.

The *Dublin Evening Mail* has followed up its first very emphatic article on the subject by another equally forcible, in which it points out the claim which the profession in Ireland has had to these distinctions, and we cordially affirm our complete concurrence in the views expressed by our contemporary on this subject. It would seem hardly necessary to argue as to the fairness of giving to the profession in Ireland the honours and distinctions proportionate in number to those granted to other divisions of the kingdom; and yet the tardiness of the Government to do justice in this matter has rendered necessary repeated protests on behalf of Irish medical men. England boasts of four medical baronets—Sir George Burrows, Sir William Gull, Sir William Jenner, and Sir Thomas Watson; one surgical baronet, Sir James Paget; two representatives of former medical baronets—Sir Benjamin Collins Brodie and Sir James Trevor Lawrence; and no less than 9 knights—Sir J. Alderson, Sir A. Armstrong, Sir J. C. Brown, Sir J. Fayrer, Sir Anthony Home, Sir Galbraith Logan, Sir William Muir, Sir James Salmon, and Sir Henry Thompson. Scotland also possesses a medical baronet, Sir Robert Christison; a representative of a medical baronet, Sir Walter Simpson; and a medical knight, Sir Alex. Douglas Taylor. In contrast with this stands Ireland, which does not number amongst its professional men either a medical or surgical baronet, nor (except the youthful successor to Sir Dominic Corrigan) a representative of a past medical or surgical baronetcy, and only three medical knights—Sir William Carroll and Sir George Owens, whose titles were the reward of civic honour, and Sir Robert Kane, who earned his laurels as a chemist. We cannot see why this slight to the profession in Ireland should be perpetuated; and inasmuch as no one can truthfully say that there are wanting to Ireland physicians or surgeons deserving of as much honour as those whose names we have quoted above, we shall await with confidence Her Majesty's choice of a medical and a surgical baronet for Ireland.

## THE ELECTION AT DR. STEEVENS' HOSPITAL.

The choice of a consulting physician and two visiting physicians to this hospital in the room of Dr. Malachi Burke and Dr. Bookey, deceased, and of Dr. Grimshaw, appointed Registrar-General, took place on Feb. 5th. The election, as we have said, acquired additional importance as involving in some degree the continued efficiency of the school which is connected with the hospital. For the office of consulting physician Dr. Grimshaw was deservedly unopposed. For that of visiting physician there were three candidates—Dr. Warren, formerly house surgeon, and now lecturer on anatomy and curator of the museum at the school; Dr. Henry Tweedy, also formerly house surgeon in the hospital, and now lecturer on medical jurisprudence in the school; and Dr. R. A. Hayes, an M.D. of Dublin University, and Fellow of the Royal College of Surgeons of last year. After considerable excitement, Drs. Tweedy and Hayes were elected to the two vacancies. There were circumstances attending this election which will compel us to revert to it next week.

# Obituary.

## DR. WILLIAM HEGARTY O'LEARY, M.P.

At the early age of 41 Dr. O'Leary, M.P., has been taken from us, after a brief illness in London of congestion of the lungs, and his death has caused quite a shock to medical circles in Dublin. Dr. O'Leary's professional life was closely identified with the Ledwich School, in which institution he, as a student, acquired that distinction which gained for him afterwards a professorship within its walls. His public position as a surgeon was as one of the medical staff of St. Vincent's Hospital, and as an examiner in surgery in the Royal College of Surgeons. On the occasion of the trial of Kelly for the murder of Constable Talbot, the medical defence was, we may say, conducted by Dr. O'Leary, and with such ability as not only to secure the acquittal of the accused, but to raise Dr. O'Leary at once into public favour. Shortly afterwards he was asked to contest the Parliamentary representation of Drogheda in the National interest, which he did with easy success, and thenceforward his private practice rapidly increased. Amongst his professional brethren he was much regarded, not only for his social qualities but for his marked ability, and even those who differed with him in politics *toto cœlo* respected and admired him for his energy and talent.

## THE LATE DR. BENSON, OF DUBLIN.

At a meeting of the Committee of Council, held at the Royal College of Surgeons in Ireland, on Tuesday, the 27th of January, 1880, Dr. Speedy, Chairman of Council, in the chair, the following resolution, proposed by Dr. J. W. Moore, and seconded by Dr. Jacob, was unanimously adepted :—

"That the Council of the Irish Medical Association have heard with deep regret of the death of Dr. Charles Benson, who for many years was the earnest friend and zealous supporter of the Association as Member, Councillor, and President. The Council desire to record their sense of the loss sustained by the Association in the removal of so valued a colleague, and, at the same time, to express their sympathy with Dr. Benson's family in their present bereavement."

◆

**Royal College of Physicians of London.**—The following candidates having passed the required examinations, were admitted Licentiates on February 16, 1880 :—

Baker, William James, 39 Claremont Square, N.
Paddle, James Isaac, University Hospital, W.C.
Shears, Charles Hartley Bedwell, St. Bartholomew's Hospital, E.C.
Stokes, Henry Fraser, 21 Compton Terrace, N.
Weed, Theodore Arthur, M.D., Wooster, 449 Strand, W.C.

## NOTICES TO CORRESPONDENTS.

Mr. Clarke.—Thanks rather long, which will be the cause of a longer delay than we should wish ; but we will find space as early as possible, on account of its interesting character.

Dr. Jeffries.—We intend reverting to the subject shortly, and will make use of his information

Royal Institution.- Tuesday, Feb. 24, at 3 p.m., Prof. Schäfer, "Physiology of Muscle.

Society of Public Analysts.—This (Wednesday) evening at 8 p.m., Dr. J. Muter, "On the Estimation of Cane-sugar in Milk."—Mr. A. Wynter Blyth, "On a New Method of taking the Specific Gravity of Solid Fats at ordinary Temperatures."—Mr. J. West Knights, "On the Action of Alum in Bread-making."—Mr. F. Maxwell Lyte, "On Blowpipe Assays of Silver Lead."—Mr. F. P. Perkins, "On the persistent occurrence of Starch."—Mr. H. Macagno, "On the Tannin of Sumach-leaves" and "A Series of Analyses of Air."

Association of Surgeons practising Dental Surgery.—This evening, at 8 p.m., Council.—8½ p.m. Mr. S. H. Cartwright, "On the Recognition of Certain Constitutional Lesions by means of Examination of the Teeth and Mouth."

Royal College of Physicians of London.—Friday, Feb. 20, at 5 p.m., Gulstonian Lectures : Dr. Gowers, "On Epilepsy."

Society of Medical Officers of Health.—This evening at 7½ p.m., Dr. G. B. Longstaff, "On some Facts bearing on the Etiology of Summer Diarrhœa."

Dr. W. Leatham.—Letter received, and will appear, if possible, in our next.

Surgeon-Major Curran.—Communication received ; its great length will, we fear, cause its insertion to be delayed.

Royal College of Physicians of London.—Monday, Feb. 23, at 5 p.m., Second Gulstonian Lecture "On Epilepsy" by Dr. Gowers.

### "A KNOT IN THE UMBILICAL CORD."

*To the Editor of the* Medical Press and Circular.

Sir,—In answer to "Inquirer" in your last issue, I may mention that after a period of forty years' medical practice it has fallen to my lot to have attended nearly 10,000 cases of midwifery, and to have met with only four cases in which a knot existed in the umbilical cord. In each the presentation was natural, the cord unusually long (exceeding 4 feet), and, with one exception, encircling the neck. No doubt many of your readers have met with nurses who would tell them that they had seen many cases of "knots" in the cord—indications of the number of children yet to be borne—but these so-called "knots" were nothing more than simple projections on the cord formed by the vessels—cellular tissue and membranous sheath, or prolongation of the chorion.

Yours faithfully,
M. Redman.
Lincoln, Feb. 13, 1880.

Royal Institution.—Thursday, Feb. 26, at 3 p.m., Prof. Dewar, "Recent Chemical Progress."

One Interested.—You cannot do better than peruse the Carmicnael Prize Essays of Mr. Rivington and Dr. Laffan ; all that is known on the subject; and all that has been done in connection with medical education will be found embodied therein.

### VACANCIES.

Belrothery Union, Kilsallaghan Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, March 5.

Buckingham General Infirmary, Aylesbury.—Resident Surgeon. Salary commencing at £80, with board. Applications to the Secretary on or before Feb. 28.

Burton-on-Trent Infirmary.—House Surgeon. Salary commencing at £130. Applications to the Hon. Sec. by Feb. 20.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary, £70, with board. Applications to the Chairman of Committee before Feb. 21.

Manorhamilton Union, Drumkeeran Dispensary.—Medical Officer. Salary, £100, with fees. Election, March 5.

Margate Royal Sea Bathing Infirmary.—Resident Surgeon. Applications, under cover, to the Secretary before Feb. 21. (See Advt.)

National Hospital for the Paralysed, Bloomsbury, London.—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary by Feb. 21.

Navan Union, Painestown Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election, Feb. 27.

North Dublin Union, No. 2 North City Dispensary.—Medical Officer. Salary, £145, with fees. Election, Feb. 23. (See Advt.)

Royal Free Hospital, Gray's Inn.—Junior Resident Medical Officer. Applications to the Secretary before Feb. 25. (See Advt.)

Royal Hospital for Diseases of the Chest, City Road, London.—Two Assistant Physicians on the Staff. Applications to the Secretary on or before Feb. 26. (See Advt.)

◆

### APPOINTMENTS.

Critchett, G. A., M.R.C.S.E., Assistant Ophthalmic Surgeon to the Middlesex Hospital.

McNeill, J. P., M.D., B.A., L.R.C.S.I., Medical Officer of Health for the Borough of Tiverton.

Mussen, A., M.D., M.R.C.S.E., Coroner for Belfast District, co. Antrim.

Poore, G. V., M.D., F.R.C.P.L., Professor of Medical Jurisprudence at University College, London.

Savory, W. S., F.R.C.S.E., M.B., Consulting Surgeon to the Charter House.

Southam, F. A., M.B., F.R.C.S.E., Resident Medical and Surgical Registrar to the Manchester Royal Infirmary.

Stephenson, W. H., M.D , L.R.C.S.Ed., Medical Officer of Health for the Blackburn Urban Sanitary District.

Tweedy, H. J. C., M.D. Univ. Dub., F.R.C.S.I., Physician to Steevens' Hospital, Dublin.

White, W. H., M.A., M.D , M.Ch., Honorary Physician to St. Marylebone General Dispensary.

Wiglesworth, H., M.B., M.R.C.S.E., Medical Officer of Health for the Ashford Urban Sanitary District.

Wright, G. A., M.B., F.R.C.S.E., Resident Surgical Officer to the Manchester Royal Infirmary.

Wright, H. C., M.R.C.S., House Surgeon to the West London Hospital.

# Abstracts
OF THE
# GULSTONIAN LECTURES ON EPILEPSY,

*Delivered before the Royal College of Physicians of London,*

By W. R. GOWERS, M.D., F.R.C.P.,

Assistant Professor of Clinical Medicine, University College; Physician to the National Hospital for the Paralysed and Epileptic.

### LECTURE I.

AFTER some introductory observations, the lecturer stated that he had chosen as the subject for these lectures some points in the clinical history of chronic convulsive diseases, as illustrated by his notes of a series of cases, sufficiently numerous, he hoped, to fulfil the conditions essential for the successful use of the method of numerical analysis. The series included cases of epilepsy, epileptiform seizures, and hystero-epilepsy; all cases of simple hysterical fits without distinct loss of consciousness, and all cases in which there was reason to suspect organic brain disease, were excluded. The hystero-epileptic cases constituted 18½ per cent. of the whole.

The first lecture was devoted to the subject of causation. Regarding the influence of sex, the proportion of 1,450 cases was found to be, females 53·4 per cent., males 46·6 per cent., nearly as 6 to 5. The excess of females was smaller, though still marked (52 per cent.) in the cases of pure epilepsy, taken separately. Of the hystero-epileptics, females constituted two-thirds. The investigation of heredity was directed to the existence of epilepsy, insanity, chorea, hysteria, and certain forms of paralysis paraplegia, and infantile paralysis. Hemiplegia was excluded as primarily vascular. The cases of hysteria or paralysis in relatives were insignificant in numbers. Inheritance was traceable in 36 per cent. (452 in 1,250 cases) and in the same proportion in the epileptics and in hystero-epileptics. Heredity influences sex; in the cases with inheritance the females were 5 per cent. more numerous than in those without inheritance. The heredity was from the father's side in 35 per cent, and from the mother's side in 39 per cent., from both in 5 per cent., and only brothers or sisters suffered in 15 per cent. The side of the inheritance influences the sex of the sufferers. The percentage of males affected was 22 per cent. greater when the disease was inherited from the father's side than when from the mother's. The reason why the females are in such excess in the inherited cases is because the inheritance is more frequently maternal, and then many more girls suffer than boys. A family history of epilepsy was obtained in three-quarters of the inherited cases. In half (240 cases) it existed alone; in 54 combined with insanity. Insanity occurred in a third (157 cases), and existed alone in the majority. Chorea occurred in relatives of 35 cases. The mother was herself less frequently diseased than the father; she was as frequently epileptic as the father, but much less frequently insane.

Phthisis has been supposed by some to predispose to epilepsy. Individual cases suggest an influence, but statistics scarcely support it. A history of phthisis in some relative was obtained in 39 per cent. of 300 cases. The proportion of phthisis was just the same in those with and those without neurotic heredity, and the percentage of neurotic heredity was nearly the same in those with and those without a history of phthisis. Signs of inherited syphilis were present in eight cases of apparently idiopathic epilepsy, and in six of these the fits began after childhood.

The influence of age was ascertained from 1,450 cases, and the percentage commencing in decennial periods was, under ten, 29; between ten and twenty, 46; between twenty and thirty, 15·7; between thirty and forty, 6; between forty and fifty, 2; and over sixty, 3; 12½ per cent. of the total commenced in the first three years of life, and 5½ per cent. in the first year. The numbers which commenced per annum fell to the sixth year, and then rose to the maximum in the sixteenth and seventeenth years, to fall rapidly after that age. The latest case was one which commenced at 71. Sex is influenced by age. In the cases commencing under ten years the females exceeded the males by 6 per cent.; in those between 10 and 20 by 18 per cent.; between 20 and 30 by 12 per cent. After this the relation is reversed. The males exceeded the females between 30 and 40 by 16 per cent; between 40 and 50 by 36 per cent.; between 50 and 60 by 40 per cent. Over 55 males only suffered. At each maximum period, both at infancy and puberty, the excess of females was very great.

The influence of heredity on age was ascertained from 1,120 cases, and found to be much more uniform than current statements suggest. Of cases commencing under 20 (844 in number) 38 per cent. presented heredity; of those between 20 and 40, 34 per cent.; and those over 40, 27 per cent. The case which commenced at 71 presents heredity, his father having been epileptic. In the first twenty years of life the disease is hereditary in a larger proportion of males than of females; between 20 and 40 by more males than females.

How far do age and sex influence the occurrence of the hystero-epileptic or co-ordinated forms of convulsion? Of 1,000 cases this form constituted, in those commencing under 10, 15 per cent. of the male and 18 per cent. of the female cases. In those commencing between 10 and 20 it formed 14 per cent. of the male and 26 per cent. of the female cases. Between 20 and 30 the percentage of male hystero-epileptics is the same; of females 21. Between 30 and 40 the male cases fell to 12 per cent.; the females rise to 26. In cases commencing over 40 this form is practically unknown in either sex. It is remarkable, however, that up to the fourth decade of life, one third of the cases presenting hystero-epileptic phenomena occurred in males.

The influence of exciting causes was then considered, and first, the cause of the large number of cases (180) commencing in the first three years of life, and facts were given to show that two-thirds of these were due to dentition convulsions, the occurrence of which was known to be largely due to the state of retarded development called rickets. Hence it seemed that the proper feeding of children would prevent a considerable number of cases of epilepsy. Of the other cases excitants were traceable in 37 per cent., and were considered in detail. 157 cases were attributed to psychical causes, and of them, 119 to fright. This cause acts chiefly under 20, and in girls than boys, but the younger the patients the greater is the equality of its action. Two-thirds of the cases were pure epilepsy, one-third hystero-epilepsy, and the proportion of hystero-epileptics is greater the shorter the interval between the fright and the fit. Other forms of excitement caused 19 cases, and anxiety 29. Blows and falls on the head caused 65 cases, exposure to sun 27, and acute disease 37. In 19 of the latter the disease was scarlet fever, and the first fit occurred in most without dropsy or ear disease; apparently from an effect of the scarlatinal poison. Chronic alcoholism caused 13 cases, and chronic lead poisoning 3. Retarded or absent menstruation was common in girls, but its influence was difficult to estimate; and the same might be said of masturbation in boys. Heart disease was not searched for in all cases, but abnormality was found in 93, undue frequency in 9, reduplication of the first sound in 13 (all young), simple dilatation in 20, simple hypertrophy in 2, and valvular disease in 30. The relation to the epilepsy varied in different cases. In 20 cases of epilepsy the patients had also had chorea, which may apparently in some cases act as a predisposing cause.

◆

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Leeds 19, Edinburgh 19, Leicester 20, Brighton 20, Portsmouth 20, Sheffield 21, Sunderland 22, Birmingham 23, Oldham 23, Glasgow 23, Norwich 24, Bristol 25, Wolverhampton 25, Salford 26, Bradford 26, Manchester 26, Hull 27, Newcastle-upon-Tyne 29, Liverpool 30, Plymouth 31, Nottingham 31, London 36, Dublin 45.

## PHLEBITIS OF THE LOWER EXTREMITIES—A SECONDARY COMPLICATION OF INJURIES OF THE HEAD.

By HENRY GRAY CROLY, F.R.C.S.,
Senior Surgeon to the City of Dublin Hospital; Member of the Court of Surgical Examiners, Royal College of Surgeons.

The occurrence of inflammation of the veins of the lower extremities, consequent on severe injuries of the head, is a remarkable and curious complication, which has not, so far as I am aware, been described or even noticed by any surgical writer. Two cases of this unusual affection having come under my observation in my private practice within the last year and a-half, I am desirous of bringing them under the notice of the Surgical Society as deserving of record.

The first case was that of Mr. K., æt. 35, who met with a severe injury of the head by having been thrown with much violence from an outside car in the town of Kildare, on the 18th of October, 1878. He was unconscious for a short time after the accident; there was arterial hæmorrhage from the left ear, vomiting of blood, and sanguineous effusion in the left mastoid region, and subsequently facial palsy, but no injury whatsoever of the lower extremities. The gentleman was seen shortly after the accident by Drs. Keogh and Chaplin, of Kildare, with whom I was called in consultation. Consciousness was soon restored, but the arterial hæmorrhage continued from the left ear for several hours. The patient suffered from the usual symptoms consequent on injuries of the head. The treatment adopted was the application of ice constantly to the head, James's powder, absolute rest, and quietness, and most carefully directed dietary. The head symptoms gradually subsided, and in a month the patient felt so well that he was approaching convalescence, and was anxious to be allowed out of bed. However, on the 21st of November, just a month and three days after the accident, he complained of acute pain in the left groin and thigh; the inguinal glands became enlarged, and very hard and painful to the touch. The pulse rose from 64, its normal number, to 100, and the temperature also rose to 100°. The foot also became swollen and painful, and the entire limb œdematous; the patient complaining much of the heavy weight, as well as the pain of the limb, which presented all the appearances usually attending phlebitis. From the 21st to the 30th of November, the pulse and temperature remained stationary at 100°; both fell gradually, and on the 13th of November the pulse fell to 64, and the temperature was normal. On the 7th of December the patient complained of pain in the opposite leg; the swelling, which followed, did not extend higher than the knee; severe rigors and perspirations occurred at the same time. The femoral and posterior tibial veins were hard and painful, and the pulse of the posterior tibial artery could scarcely be felt behind the internal ankle. The treatment adopted was leeches to the groin, anodyne draughts, hot sedative fomentations, linseed poultices, and elevation of the leg. The whole limb was wrapped in wadding, followed by stimulating and anodyne embrocations, besides friction and careful bandaging with flannel rollers, nutritious diet, and quinine. The patient gradually and slowly recovered (but both legs, especially the left, remained swollen and œdematous for several weeks), and is now in good health, and able to walk as well as ever.

I had the advantage of a consultation in this case with Dr. Robert M'Donnell, who concurred in my views on the subject, viz., the likelihood of fracture of the left side of the base of the skull having occurred, and that the phlebitis was a consequence of the injury.

Case II.—Miss ——, a young lady residing at . . .

---

(a) Read before the Surgical Society of Ireland.

. . . . . in the county Westmeath, was thrown violently from her horse against an iron gate on the 12th of September, 1879. She was stunned, and was found to have received a very severe scalp wound, laying bare a large portion of the right parietal, temporal, and frontal bones. In addition to the usual symptoms resulting from concussion, she complained of intense pain in the nape of the neck. She was seen shortly after the accident by Dr. Longworth, of Moat, who carefully examined her, arrested the hæmorrhage, and dressed the wound. On the following day I was summoned by the lady's father by telegram, to attend with Dr. Longworth. Considering the very severe concussion and extensive wound, both requiring vigilant care, the case progressed as satisfactorily as could have been expected, and no complication of a serious nature ensued until the third week after the accident, when the patient was attacked with a very severe rigor, and subsequently complained of acute pain in the left inguinal region, extending subsequently down the thigh, leg, and foot. The femoral vein was hard and exquisitely painful, as in the previous case; the whole limb became very much swollen and œdematous; pulse and temperature rose with the symptoms; severe rigors and perspirations having also occurred, with the exception of leeching, the same line of treatment as in Case I. was adopted. At the end of about the tenth week the patient complained of sudden and sharp pain near the right breast (without any apparent cause), which proved to have been acute pleuritis, which yielded to treatment. At the end of the twelfth week from the date of the injury, the wound having thoroughly healed, erysipelas attacked the right side of the face, being the same side as the wound. This attack soon subsided. The renal secretion in both cases detailed was free from albumen. This case is still under treatment, and although the young lady has recovered her health very materially, the affected limb remains weak and heavy, and portions of the vessels hard and woodlike to the touch, for which the repeated application of vesicating collodion has been adopted with benefit.

The similarity of symptoms in cases No. I. and II. is very remarkable; the phlebitis having set in subsequent to the disappearance of all the head symptoms. The complication must be very rare, not being related or even alluded to in the writings of surgical authors. I communicated the facts of these cases to the following eminent surgical writers—Messrs. Erichsen, Prescott Hewett, and Bryant, of London. The following are their replies:—

My Dear Sir,—The cases of phlebitis following injuries of the head that you mention, are most interesting, and certainly deserve record. They doubtless belong to the same category of secondary blood changes that reach their culminating point in abscess of the liver as a sequela of head injuries. But as affecting the veins of the lower extremity, they must be rare, as I do not recollect to have met with, or to have heard of, a case of the kind.

I am, my dear Sir,
Most faithfully yours,
John Eric Erichsen.
6 Cavendish Place, Cavendish Square, W.
December 14, 1879.

My Dear Mr. Croly,—Your cases of phlebitis of the femoral veins after head injury are curious, and, I think, rare; I know of no such instances. The older surgeons used to put abscess of the liver and head injuries together as cause and effect, but phlebitic troubles as effect are difficult to explain. You should publish the cases.

With kind regards, believe me,
Sincerely yours, Thomas Bryant.
53 Upper Brook St., Grosvenor Square.
December 13, 1879.

My Dear Sir,—As to the cases which you mention, phlebitis of the lower extremity, following severe injuries of the head, I cannot recall to mind having met with such cases. They are interesting ones, and ought certainly to be put on record.

Yours very truly,
Prescott Hewett.
1 Chesterfield Street, May Fair.
Jan. 15, 1880.

My Dear Croly,—Refering to Miss —— case, a violent rigor ushered in the attack of acute phlebitis of the veins of the left lower extremity. The limb became enormously enlarged and œdematous, with pain and tenderness along the course of the veins. A similar rigor was the precursor of pleuritis, and erysipelas of the face and scalp was the next complication. The affected leg still continues powerless and heavy, but reduced to the natural size. At the time of the accident I made a careful examination of the extremities; not even an abrasion or ecchymosis was observable. I fear it will be impossible for me to be up on Friday.

Sincerely yours,
P. Longworth, F.R.C.S.
Moat, Jan. 28, 1880.

## ON CONTRACTIONS OF THE MOUTH. (a)

By E. D. MAPOTHER, M.D.,
President Royal College of Surgeons; Surgeon to St. Vincent's Hospital; Consulting Surgeon to the Dental and Children's Hospitals, Dublin.

During the past three months cases of contraction of the jaws and oral aperture have occurred to me which may interest the Society, especially the first, which relates to the branch of surgery lately affiliated with our College.

A lady, aged 24, married, and mother of one child, consulted me for closure of the jaws, which had been increasing for eighteen months from March, 1878. Then there had been toothache of the second and third left inferior molars, but no abscess or other inflammatory condition. The central incisors could be only separated for two lines, and any attempt to force them apart caused severe stretching pain. Speech was very imperfect, and for months she had been fed with fluids sucked from the point of a teaspoon. She was therefore weakly because underfed. The left masseter felt through the skin very hard, and its anterior border, examined through the mucous membrane, was extremely rigid. The right muscle was softer, but also in tonic spasm.

As antispasmodics had been fully tried by two leading physicians, and as further closure, to the total exclusion of food, was dreaded, I urged examination during anæsthesia, and the aid of Mr. Baker, F.R.C.S., was procured. When etherisation was complete the jaws could be fully separated, and the dilators we had ready were not needed. They were of the kink invented by the late Mr. Maunder—a boxwood cone with a spiral groove, just like the Rostellaria shell—and the steel two-bladed one. Mr. Baker extracted the wisdom tooth, which was impacted in the root of the coronoid process and the second molar, which it had displaced and diseased. For a few days there was soreness in moving the jaws. Last week I saw that she could fully enjoy a yawn, and that, having chewed solids, her health greatly improved.

The Americans term this disease *trismus dentium*, and the words *sapientiæ inferiorum* may with exactness be added, for it is these teeth alone which excite it. The upper wisdom teeth can make room towards the tuber or antrum, but the coronoid process is less yielding when eruption is hindered by crowding of the teeth owing to want of growth backwards of the ramus. At the age of six years the sacs of the lower wisdom teeth appear, and at twelve calcify in the middle of the coronoid process. It is quite common for teeth to remain half-erupted, and covered by a flap of gum, which causes much pain in mastication, and leads to caries, as noted in John Hunter's great work on the teeth (1778), which constitutes him the father of dental pathology. Malposition of these teeth has produced pharyngeal and sub-fascial abscesses so severe as to threaten life, and connective nerve symptoms like aphonia and amaurosis. They lie so close to the inferior dental nerve that it has been torn during their extraction. The great size of this nerve, and its close connection with the twigs to the masticatory muscles, explain spasm of them, especially as their antagonists, the muscles which open the mouth, are weak and indirect in action.

---

(a) Read before the Surgical Society of Ireland.

It is reported that metal stoppings, especially those of both the positive and negative conditions, have excited electrical trismus of the masseter. Dr. G. Johnson relates that a grain of flint lodged for fourteen days in a scar in the cheek caused trismus, and, what seems inexplicable, palsy of the seventh. Allusion may be made to other causes of trismus. The buccal, mainly a sensitive nerve, forming a plexus with the facial; epilepsy in this case had recurred after a lapse of twelve years, but removal of the irritant cured all. Barwell found it unilateral from a temporal wound, and with the peculiarity of relaxation during sleep. The literature of trismus nascentium is so familiar that I will only remark that tetanus, spasm of other muscles, supervenes if the infant lives long enough, and that some of its assigned causes could act through the cutaneous branches and the inferior maxillary division of the fifth nerve. Cold to the face, the only exposed part, chill after very hot baths—causes said to have respectively produced the great Iceland and Vienna epidemics—might be thus regarded. The foul air pent up in the Rotunda one hundred years ago, and the effluvia from filth round Negro babies, would act on the eighth nerve, and pressure of the occipital bone during parturition upon the respiratory nerve-centre, as urged by Marion Sims, would lead to spasm of the muscles of the mouth, pharynx, and chest. Causation by inflammation about the navel, as assigned by A. Colles, is beyond neurological speculation.

The treatment in my case was simple and effectual, yet by some, gradual separation by means of a wedge, or of Cattlin's rack and pinion separator, is preferred; and the masseter has been subcutaneously divided in one instance, the closure being so extreme that the patient had to put the lips into fluid food and suck up like a pig. In another case the digastric, a weak antagonist, has been excited by galvanic needles stuck into it.

It is rash to point a moral from a single case, but I believe most serious troubles could be avoided by the diagnostic power which a course of lectures on dental pathology would confer on every member of our profession.

*Stomato-plasty.*—Last October a countryman, aged 30, otherwise healthy, was sent by Dr. Lyster, of Athlone, to St. Vincent's for contraction of the oral and nasal openings, the result of lupus, which had cicatrised two years before, with horrible deformity. The left nasal opening was wholly closed with a thick scar, and in the right there was a passage through which he daily forced a piece of wood the size of a No. 2 catheter. He refused all interference with the nostrils, as he said that by the use of caustics the contractions had been made worse. The oral aperture was a perfect circle of six lines in diameter, with healthy lip-tissue at the upper and lower thirds, but with hard cicatricial structure at the commissures. It was scarcely dilatable, and examination of the mucous surface with the little finger caused much difficulty of breathing. Speech was very imperfect, and he had been restricted to fluid diet for months. As he begged for the least severe operation, a plan was followed which I have found useful in dealing with cicatricial webs after burns of the elbow and neck. In each cheek, six lines from the strictured mouth, a perforation was made with a platinum rod, two lines in diameter, heated to whiteness by the benzole apparatus. The buccal cavity was protected by a wooden spatula. Mr. Morrison, F.R.C.S.I., has made such holes with Chassaignac's trocar, and kept them open with a drainage tube acting like a seton. In five days the sloughs came out, leaving holes apparently too large. They quickly contracted to a size less than the platinum rod, and in a month were healed, with smooth flexible tissue, which seemed as likely to be permanent as the perforation in a lady's ear. Then the intervening pieces were removed by incisions from the upper and lower edges of the holes to the mouth. On the left side the cheek was found very thick, and at the suggestion of my colleague, Mr. O'Leary, I followed the plan of Serre, of Montpellier, and took out a wedge-shaped bit of each cut surface from between the skin and mucous membrane, which were then sutured. In four days the surface of the right aperture ulcerated, and contraction ensued till the plan on that side was a failure. The patient and I were fairly content with the left operation, which widened the mouth by some three lines, but on the right (Dec. 9) I performed Dieffenbach's stomato-plasty. I find that Werneck adopted this procedure in 1817—thirteen years before the great master just named.

Anæsthesia was not attempted on this or the former occasion, as the breath inlet was so narrow. The left forefinger being passed towards the mucous surface incisions were carried from a point ten lines external to the commissure to the upper and lower edges of the mouth. They went only to the depth of the sub-mucous tissue, and to this level the triangular piece was dissected off. The labial portion of the orbicular muscle was cut away, for its sphincter action seemed to promote the persisting contraction. The superior coronary artery being divided was twisted. The mucous membrane, made tense by lowering the jaw, was cut horizontally to within two lines of the angle, with a scissors, and the flaps were stitched to the edges of the skin. But for the difficulty of breathing, I would have followed Velpeau's plan of inserting the sutures before dividing the mucous membrane. Towards the new commissure the flaps were very narrow, but to get them wider would have required incisions beyond the level of the healthy lips. The jaw was bound up with a roller. All was fairly healing by the fourth day; the sutures were removed, and a mouth-stretcher, or tubular obturator, similar to that figured in Garretson's "Oral Surgery," but made of gutta-percha, was put in. The gutter all round kept it fixed, and the opening in it was much larger than the mouth before operation. He wore it very perseveringly, only removing it when feeding. On Christmas eve, when he insisted on going home—some eighty miles—the mouth measured transversely sixteen lines, and when opened to the utmost fourteen lines from above downwards. Its greater extent to the right side was not very unsightly, and it will probably lessen. The newly-formed lips had a fair red colour. During treatment the surface of the scar got abraded in several points, yet no lupoid ulceration recommenced, because the sebaceous glands, in which that process has its site, had been all destroyed.

## JERVIS STREET HOSPITAL, DUBLIN.

### *Wound of Terminal Branch of the Radial Artery—Gangrene—Amputation of the Arm—Secondary Hæmorrhage—Ligature of a Double Axillary Artery.*

Under the Care of Dr. AUSTIN MELDON, F.R.C.S.I.

Reported by JOHN CASHIN, L.R.C.S.I., Resident Surgeon.

C. D., a carpenter, æt. 23, unmarried, residing at Kilcock, co. Kildare, was admitted into Jervis Street Hospital on April 1, 1879. The history of the case was as follows:—

On the 26th of March, in attempting to strike a comrade, with whom he was quarrelling, his hand passed through a pane of glass which inflicted a lacerated wound, extending from cloacas space to the phalangeal joint of the thumb, dividing one of the terminal branches of the radial artery. The hæmorrhage was very great, and before he saw the dispensary medical officer he lost a considerable quantity of blood. Styptics and well applied pressure on the radial and ulnar arrested the hæmorrhage, but as soon as this was removed the bleeding recommenced. Five times within the next few days it recurred. Each time he lost a large amount of blood. On admission into hospital, he was blanched, very weak, and the pulse almost imperceptible.

I had him placed in bed and immediately removed the compresses from the brachial, radial, and ulnar arteries. For some hours after his admission there was no return of the hæmorrhage; but at 4 o'clock I was summoned to his bedside and found him bleeding; I stripped the wound and arrested the hæmorrhage by plugging with lint and compound tincture of benzoin. Dr. Meldon saw him on the following day at the morning visit—ordered iron, quinine, and opium, and directed that the wound should be dressed with turpentine; a resident pupil was left at his bedside, and directions given to send for Dr. Meldon should bleeding again occur. During the night the patient had severe rigors, and on the following day erysipelas was developed. This terminated in gangrene, which spread rapidly from the fingers. It was decided in consultation to amputate the arm, and the operation was successfully performed by Dr. Meldon, who, owing to the œdematous condition of the arm, removed it very close to the shoulder. A drainage-tube was put between the flaps, and the vessels tied with strong catgut; there was rather severe hæmorrhage from the medullary canal, but this was controlled by a small plug of lint. The stump was dressed antiseptically.

On the fifth day all was healed, but the two angles where the tube and ligatures were brought out.

On the evening of Sunday the 20th, I was called to see the patient, and found arterial blood flowing freely from one these angles. I immediately raised the stump, put a pad upon each flap, and bandaged it tightly; this at once stopped the hæmorrhage. Next morning the dressing became saturated with blood, and Dr. Meldon, who had just arrived, stripped the stump, and easily arrested the bleeding by pressure and elevation. That evening it again bled, and as the patient was now very feeble, he determined to tie the axillary. Assisted by Dr. Stoker he made an incision of about 2 inches long through the anterior wall of the axilla, avoiding the cephalic vein, scraped carefully through the areolar tissue, and in a few seconds found the vessels and nerves—the vein was then drawn inwards and the artery, which was of very small size, insulated and tied. The stump was then left exposed, and it was found the bleeding was arrested. For about an hour all seemed well, and Dr. Meldon was about to leave the hospital, when he found a little arterial blood was coming from the other angle of the wound. Remembering the small size of the artery he had tied, and fearing high up bifurcation, he sought and found the second axillary artery, which he tied; now all hæmorrhage ceased, and the patient took a good deal of nourishment during the night, but towards morning he spat up some blood, and soon after died.

In his remarks to the students Dr. Meldon said he looked upon this case as one of those all surgeons feared viz, a patient of a hæmorrhagic diathesis. He showed upon post-mortem examination that the bifurcation had taken place in the first state of the axillary, and that both vessels had been secured in the third stage.

## HARVEIAN SOCIETY OF LONDON.

The President, Henry Power, Esq., F.R.C.S., in the chair.

### CASES IN GYNÆCOLOGY.

Dr. Alfred Meadows read accounts of several interesting cases. The first was that of a married woman, æt. 46, who had scanty menses, and was childless. She felt a pain in her pelvis, which she attributed to strain. There were present constipation and tympanitic distension, simulating pregnancy at times. The uterus was pushed backwards by a tumour as large as an egg, and of sarcomatous feel. He had observed excessive tympanitis with constipation as early indications of malignant disease in the pelvis. The second case was one of menorrhagia in a single woman of 26, whose menses had always been free, latterly of seven days' duration, and coming on at intervals of ten days, with severe leucorrhœa in the interval. There was tenderness over both ovaries. Astringents, especially ferruginous, had been given without good effects. Medicines which retard ovulation were indicated in such cases, as the iodides and bromides of the alkalies. Under the bromides of potassium the catamenia quickly became of normal duration, every twenty-eight days. The third was a case of a dressmaker of 20, who was not well after she came up to London from the country. Her catamenia fell off, her mammæ diminished in size, and she became pale and weak. She had iron, quinine, and tinct. lyttæ, and soon got well. The fourth was a young female who had suffered "a disappointment," after which there was pain with tenderness over both ovaries, the left being the worse of the two. This case improved rapidly under vaginal pessaries containing conium, which Dr. Meadows said was a powerful local sedative in these cases. Cantharidine blisters in these cases he regarded as too irritant.

The President, Drs. Fitzpatrick, Fothergill, and Cripps Lawrence made some observations, after which Dr. Meadows replied, pointing out the contrast in the above cases.

### VENESECTION.

Dr. Broadbent then read the paper of the evening, on *Venesection.* He pointed out that the fluctuations of medical practice were unfortunate, though some of them were warranted. Bleeding from being practised indiscriminately has fallen into disuse, though it is often of striking power, and is accompanied by very little risk. It does not in inflammatory affections strike at the inflammation directly, but lowers the blood pressure in the arteries. When an aneurism is threatening life, bleeding will relieve the tension within its walls, and thus is useful as a palliative. In overdistension of the right heart bleeding is very useful. In those cases of pneumonia where the patient becomes pale, gasps for breath, and is unable to lie down, where the heart beats violently while the pulse is small, then bleeding is indicated, and as the blood flows the pulse improves. He had not bled in bronchitis. In chronic bronchitis with emphysema it did little good. In aortic valvular disease it was not called for. In mitral regurgitation digitalis was to be preferred; but in mitral stenosis the question of bleeding often arose, especially with liver pulsation. Dr. Broadbent then examined at some length the causes of high arterial tension when bleeding is indicated. When the pulse is full betwixt the beats and feels like a tendon, than bleeding is indicated, as in uræmic convulsions, in convulsions at times without uræmia, in scarlatinal albuminuria, in pregnancy, &c. It was also useful in amenorrhœa in plethoric individuals. The two main indications for venesection are —(1) distension of the right ventricle; and (2) high arterial tension.

The President, Mr. Sedgwick, Dr. Alderson, and Mr. Raynor took part in the discussion which followed, after which Dr. Broadbent replied.

The meeting then adjourned.

## SURGICAL SOCIETY OF IRELAND.

A meeting of the Surgical Society of Ireland was held on Friday evening, January 30th, in the Albert Hall, Royal College of Surgeons, Dr. Mapother, President of the College, in the chair.

Mr. B. Wills Richardson read the minutes of the previous meeting, which were confirmed.

### THE LATE DR. BENSON.

The President.—Gentlemen, at our last meeting there sat here our senior member, our only surviving founder of this Society, and one of the most respected members of the profession in Ireland. A few days afterwards Dr. Benson passed away. On consultation with other officers of the Society it was thought unadvisable to postpone the present meeting, as his interment had already taken place, and that with every demonstration of respect which the College could confer upon him. Some future period will be more fitting than the present for detailing the career of our lamented member, which was indeed conspicuous for earnest work and most shining honour, Mr. Henry Gray Croly read a communication on

### INFLAMMATION OF THE LOWER EXTREMITIES FOLLOWING HEAD INJURIES.

which will be found on page 144.

Dr. Robert M'Donnell corroborated the account of the symptoms given of the first case which he saw, and said he had never witnessed anything of the kind before. He could hardly exclude the relation of cause and effect between the head injury and the inflammation of the hip. Nevertheless the cases were well worthy of record as forming the central nucleus round which others might be collected.

Mr. W. Thornley Stoker thought the cases were capable of a certain explanation by reference to the history and pathology of a complaint with which most were, to some extent familiar, namely, phlegmasia alba dolens, or milk leg. At this period of the nineteenth century there could be little doubt the phlegmasia dolens was essentially in the first instance a phlebitis. A great many theories were put forward as to what might be its cause; and a great many pathologists were agreed that other parts became involved. It was in the first place a phlebitis of the femoral or other large veins in the neighbourhood. Phlegmasia dolens was not a disease necessarily following parturition. Cases of it had been recorded in constitutional exhaustion; it had followed prolonged suffering from fever, and in parturition cases it had been known to occur after post-partum hæmorrhage. To account for the post-partum phlebitis a theory was that the vessels having become rapidly empty of their healthy blood, there was a recuperative effort to fill themselves with distending fluid which did not represent the normal state of the blood. Again it was to be remembered that phlegmasia dolens was a disease that sometimes occurred at a considerable period after parturition, even as late as two or three weeks, if not later. He saw no reason why the conditions that occurred in Mr. Croly's cases could not be explained in the same manner as the theory put forward in phlegmasia dolens. In Mr. Croly's cases the disease occurred in the lower extremities, and in the left limb; and it was reasonable to expect where the disease was referable to the blood that it would occur where stagnation was most prone, and in the left leg the vein was subject to pressure from its relation to the rectum, which passed through the pelvis, a pressure to which the right side was not subject.

Mr. Ed. Hamilton said it appeared that one of the early symptoms in the first case was inflammation of the glands in the groin, and he asked did the same observation apply to the second.

Dr. Henry Kennedy mentioned the case of a lady who had broken the neck of her thigh bone. About three weeks afterwards he was surprised to find her suffering from pain in the other leg, and on examination he discovered symptoms of phlebitis; but fortunately the disease did not go to an extreme length. There was considerable swelling and great pain in the thigh, groin, and calf of the leg; and at the same time also fever rose. He had read of cases of injuries of the head resulting in death, and the veins of the skull and the sinuses, too, had been found filled with pus, and occasionally with lymph; and he had seen phlebitis in every form, and after every form of fever—typhus, typhoid, diabetes, but still so unequivocally marked, there was no mistaking the disease—rapid increase of fever, great swelling, intense pain, and local pain on pressure. So often had he seen it in connection with the diet, he had regarded them in the relation of cause and effect. Nowadays milk diet was given in chronic disease, but he had seen many cases in which that form of diet, when overdone, was likely to lead to the disease in question. At times it assumed the extent of an epidemic. He had had four in Cork Street Hospital under his treatment. Mercury he found of great use, and he took the hint from his namesake when Master of the Lying-in Hospital. Salts of ammonia he also found most useful in softening the veins and causing absorption.

Mr. Stokes had great doubts as to whether there was any connection between the head injury and the secondary phlebitis that occurred in both instances under circumstances that, so far as he was aware, had not been previously recorded. He asked whether in the first instance there was any gouty tendency in the patient? That question he asked having regard to a case in his own practice about three years ago. A gentleman fell down the stairs of an hotel and contused his right knee. He was in a hurry home, and the gentleman called in put the limb up in a starch bandage and sent him home. Then he came under his (Mr. Stokes's) treatment, and after a fortnight the knee became perfectly well. However, a week later he was suddenly called to visit him, and he found the limb enormously swollen. He did not think there could be any connection between the inflammation that had set in and the original injury. Such a great length of time had elapsed between it and the occurrence of the phlebitis, and he regarded it as gouty phlebitis, the gentleman having had previously an attack of gouty leg. In this opinion Dr. Hudson fully concurred. Eventually the gentleman got perfectly well. He was inclined to think the phlebitis in the cases under discussion was in connection with that tendency, or, as Mr. Hamilton had called attention to, the result of inflammatory enlargement of the inguinal glands. In reference to the second case he thought the phlebitis came on in the same way as Mr. Stoker had described, after great exhaustion, fever, extensive hæmorrhage, or parturition.

Dr. M'Clintock had peculiar interest in the cases from their great similarity to phlegmasia dolens occurring after parturition. *A priori* he would say if injury of the scalp was capable of giving rise to abscess of the liver, a fact as well established as any other, it would be capable of inducing the obscure disease, phlegmasia dolens, the exact pathology of which had not been discovered, but the most accepted theory was that it depended upon an altered condition of the blood. Phlegmasia dolens was apt to follow profuse loss of blood in parturition, and it might occur in natural labours after the lapse of three, four, and five weeks, as he had himself many times seen. It was long supposed that phlegmasia dolens was traceable to some disease spreading from the uterine veins to the femoral veins. However, that theory was no longer maintained. Several years ago he himself published an important and interesting case where true phlegmasia dolens occurred in the arm after parturition, which certainly could not be traced to any contiguity of the disease in the uterine veins. However, the idea of its being consequent on injury of the head was wholly contradicted by the experience of all writers on the subject. So far as the discussion went no one had recorded any such case. Another noteworthy point was the occurrence of the two exceptional cases within a comparatively recent space.

Mr. H. G. Croly replied: He said the discussion did not lead him to any more satisfactory conclusion than he had arrived at before; and whether his were cases of phlebitis following head injuries, or were merely coincidents, it was still difficult to determine. However, if severe hæmorrhage from scalp wounds were to cause phlegmasia dolens of the lower extremity, they would have seen many cases of it. In his own mind he had no doubt the inflammation was caused by the injury of the head, whatever the condition of the blood was, and he had also no doubt that his were cases of genuine phlebitis. The glands in both cases were enlarged, the inguinal gland being more in the track of the femoral vein. Last Saturday week about two inches of the femoral vein were hard as a pen, and he had been softening it down with vesicating collodion as long as the hardness remained. He thought very few doubted that pleuritis was the consequence of injury of the head. The connection with the lungs could be easier traced than with the lower extremity. With his cases there was no gouty connection whatever, none of the families being gouty. He adhered to the opinion that the inflammation was consequent on the head injury, but could come to no satisfactory conclusion as to the real cause of the affection. At all events his object was to place the cases on record rather than to attempt an explanation of them.

Dr. M'Clintock, Vice-President of the College, having taken the chair,

The President read a paper on

### CONTRACTIONS OF THE MOUTH AND JAWS.

which will be found on page 145.

Mr. Baker had little to add to the case which had been brought before the Society by the President, and with which his name had been associated. With all deference, however, he must differ with Dr. Mapother as to the cause of the muscular spasm in this case. He did not think it was due to impaction of the wisdom tooth, but to "contiguous irritation." The wisdom tooth was perfectly erupted and standing well in front of the coronoid process. Both the wisdom tooth and the second molar were extensively diseased, and their fangs showed evidence of long-standing chronic inflammation. The periosteum was considerably thickened. and almost cartilaginous in its consistence. In cases of this kind, after the removal of the teeth which were the source of irritation, there was generally a recurrence of the spasm in an aggravated form consequent on the increased irritation from the operation. This state of things soon subsided, and eventuated in a satisfactory cure. The instrument used to separate the jaws in this case was Fergusson's double-lever gag; the teeth were removed with a slightly curved elevator.

Mr. **Robert M'Donnell** said he had had recently under his care in Steevens' Hospital a case so closely similar to the second that he really thought it was the same until he found that Dr. Mapother's was a male, while his own was a female. His was a frightful case, in which the face had been almost entirely devoured away; and the mouth, which was kept open by a crow's quill, had reduced so that he could barely insert his little finger. In fact, she was able to take food so badly that she was dying for want of nutriment. She had been operated on by dilating the mouth, but resulting in her being rather in a worse position than before. There was no mucous membrane existing on the inside of the lips. He did not think the case was suitable for the operation Dr. Mapother had alluded to, and he contented himself with a very simple proceeding, which, owing to the assiduity and ingenuity of the resident pupil (Mr. Isdill), turned out very well, and the patient went away greatly improved. He slit the mouth across very widely and put in silver sutures, but they were absolutely of no use. After a few days it was difficult to prevent it from healing. The resident pupil then made silver wire hooks and fastened them with an india-rubber strap behind. However, the patient endured them and went home again very imperfectly cured, but still with a much better mouth than she had when she came to town. The first case was extremely interesting. It recalled a remarkable case of closure of the jaws—that of a gentleman who was wounded in the shoulder in India, the head of the humerus being injured. On his way home by the Cape of Good Hope his jaws began to close, closing gradually and steadily with occasional relaxations sometimes for a few days. The ball had remained lodged about the shoulder joint. In London he consulted Sir William Fergusson; and having been placed under the influence of an anæsthetic, an attempt was made, but without success, to get out the ball. Irritation of the circumflex nerve probably gave rise to the symptoms. Coming to Dublin some time afterwards he was under his (Mr. M'Donnell's) care, and that of the late Mr. L'Estrange. They succeeded in opening his mouth with dilators, so that he was able to eat solid food carefully minced. Still, no treatment could reduce the irritation, for which they could discover no other cause than the injury mentioned. By a surgeon in London he had been placed under a severe mercurial course, under the supposition that neuritis was the cause. As the result, the anterior part of the alveolus became carious. The trouble of putting in food produced a tenderness which gave rise to necrosis of the front of the jaw. However, by this treatment he obtained a sufficiently good opening to eat with. Subsequently he returned to India and died in the course of some years, having never recovered the trismus.

Dr. **Stack** said the two cases brought forward were of extreme interest both to the general and the special surgeon. The former of the two, that which was concerned with the wisdom tooth, was the one on which he would make one or two remarks: The cause of the stiffness of the jaw in this and similar cases seemed to be either a spasmodic contraction of the masseter muscle or an interference with its power of relaxation, due to an infiltration of the products of inflammation into or around its sheath. In the case in question the former appeared to have been the condition of the muscle, because, under ether, the tension relaxed and the jaws were able to be separated rapidly by the gag. If the stiffness of the jaw in any such case were due to the presence of inflammatory products, rapid separation of the jaws either with or without an anæsthetic would be impossible; or, if possible, could only take place after such rending and laceration of the tissues by the orcible distension as would render such an attempt very nadvisable. As regards the wounding of a nerve in operations on the wisdom teeth, it seems to him that the gustatory nerve was in more danger of being wounded in such operation than in the inferior dental.

Mr. **Stokes** said he himself had performed the operations of Serrè with good results; but he was not aware that the same mode of treatment had ever been adopted before in the class of cases detailed, and it would be particularly interesting hereafter to see whether the result would be as satisfactory as it was at present. In his operation he found while relief was given there was a tendency to recontraction to a certain extent, and Dr. Mapother's would be interesting in enabling him to compare the two classes of cases in the same individual.

Mr. **Croly** had met with several cases of abscess connected with the wisdom teeth, to which his attention was first directed by the late Professor Geoghegan, who was in the habit of making incisions, giving instant relief. Within the last few weeks, from a licentiate of that College, he received a letter requesting a visit, as he was suffering from tonsillitis and almost starved. He saw him. Looking into his mouth, disclosing a very peculiar V-shaped palate, he found the tonsils free, and he then pressed over the last wisdom tooth of the left side of lower jaw, and making a free incision gave him instant relief. About a fortnight afterwards he was attacked with acute inflammation over the situation of the wisdom tooth, and then he got an attack which he thought was tonsillitis. There was great difficulty in looking into his mouth at all, his teeth were almost locked. In a chink between the teeth matter had formed, which originated in the inflammation in connection with the wisdom teeth. Through that chink he got in a bistoury and made an incision, which gave great relief. Since then he had consulted Mr. Sherlock, who was present.

Mr. **Sherlock** said the patient sent him by Mr. Croly was quite well and could open his jaws sufficiently wide to take solid food, but the tooth was not removed. He thought the irritation was caused by the second molar tooth rather than by the wisdom tooth. However, the patient declined to have either removed as he was quite relieved at present.

The **President** acknowledged the very important information that had been contributed on the subject, especially by the members of the dental profession, and he at once yielded to Mr. Baker's superior knowledge with regard to the dental pathology. At the same time in the case in question there had been no inflammatory action, nothing like effusion of lymph, round the masseter muscle. It seemed to be as pure a case of reflex spasm of the masseter muscle as could be conceived. Immediately after the extraction the alveolus of the wisdom teeth was fairly in front of the coronoid process. The impaction of the third molar in the root of the coronoid process was usually the cause of *trismus dentium*. On looking at the skull of a child, æt. 4½ years, where its first molar lay under the root of the coronoid process, its impaction in that position caused many of the troubles that he had detailed. In the details given by Mr. M'Donnell he was much interested, and he recognised the extreme difficulty there was from the condition of the mucous membrane, and where the two holes had failed. But his own case was particularly trying from the difficulty of examining the oral aperture, owing to the closing of the two nostrils. At each attempt the man got blue in the face, so that he never could make any examination of the mucous membrane. He was much pleased at the suggestion made about the hooks pulling back the new commissure. A good deal of the persistent action depended on the sphincter-like action of the orbicularis oris muscle. He had alluded to the absence of infiltration or other inflammatory condition in his case. With regard to the anatomy of the inferior dental nerve, that nerve was more in the way in the extraction of a wisdom tooth than the gustatory, and more likely to be injured. No tugging force from above would rupture the gustatory nerve. Rupture was recorded by Mr. Salter; it occurred in the person of a German baron. The moment the nerve was ruptured he exclaimed that his jaw was torn away. The inferior dental nerve having been torn, the nerve was rendered quite anæsthetic. Mr. Stokes' observations were thoroughly sagacious, and he would promise, if the Society felt interested, to record any further observations in the case. Dr. Lyster, of Athlone, had informed him that the man had a mouth as large as when he left hospital, but he was persistently wearing the tubular dilator. In reference to Mr. Croly's observation, the case they had been discussing was not one of closure of the jaws through abscess, but was a pure case of spasm of the masseter muscle by reflex irritation of the inferior dental nerve.

The Society then adjourned.

◆

## STATISTICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

At the last monthly meeting held on Tuesday, the 17th instant, Sir Rawson W. Rawson, C.B., in the chair,

Mr. Thomas A. Welton read a paper on

### CERTAIN CHANGES IN THE ENGLISH RATES OF MORTALITY.

He commenced by referring to the manner in which permanent but gradual changes affecting mortality may be obscured by those variations which arise from transient causes of disturbance, and which for the moment are more considerable, and showed that since 1846-50 there has been a reduction in the English rates of mortality of both sexes between the ages 5—25. That the rates of mortality amongst males at ages 35—75, after being somewhat diminished, have become higher than they were, to the extent of 15 or 20 per cent. above the minimum. But that amongst females the tendency towards increased mortality at those ages is barely observable. Proceeding to test the matter by constructing tables of mortality, according to the experience of England and Wales in each quinquennial period since 1841-45, it appears that there has apparently been an increase of male mortality at the higher ages sufficient to counterbalance the improvement in early life, and even after a time to turn it into a loss; whilst among females a more than proportionate improvement in early life has been followed by a condition of things at the higher ages which leaves the gain practically undiminished. This has brought about a great change in the relative mortality of the sexes, insomuch that whilst in 1856-60 the average ages at which the numbers born were reduced to one-half, were—

Males, 46.5 years } difference 2·4 in favour of females,
Females, 48·9 ,, }

according to the experience of 1871-75, the figures would be—

Males, 45·8 years } difference 5·1 in favour of females.
Females, 50·9 ,, }

Showing that whereas, according to the English life table, a certain number of males and females respectively would survive out of a fixed number of births, to be counted at a census as being aged 75—80, viz.: 288,993 males, and 333,526 females, the experience of 1871-75 points to the survival of no more than 264,475 males, but an increased number of females, viz., 356,199. The tendency towards an increasing excess of surviving females at high ages, as compared with the numbers of males attaining such ages, seems to have steadily gained strength throughout the thirty years ending with 1875. Turning to the causes of this state of things, Mr. Welton showed that there has been a steady increase during the whole of the period in male mortality after 35 years of age by diseases of the lungs, heart, and brain, and also the less important diseases of the kidneys, and cancer. Such increased mortality has been so general, even in the rural divisions of the kingdom, that it seems difficult to attribute it to the increased strain upon the vital energies occasioned by modern conditions of life; but he did not attempt to assign a cause for the changes which have taken place, nor for the fact that the mortality from consumption (phthisis) has remained almost stationary, whilst lung disease has become so much more fatal.

◆

Different forms of violence caused no less than 81 deaths in London last week; 75 were the result of negligence or accident, including 18 of infants overlaid. Affections of the respiratory organs caused 1,020 deaths, being about double the average for the last ten years. Deaths from diseases of the zymotic class were 339, 98 above the corrected average.

## AN ANALYSIS OF RECENT ADDITIONS TO OPHTHALMOLOGICAL LITERATURE.

By ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

(*Continued.*)

Passing over a long illustrative chapter devoted to "practical examples in the determination of accommodation," we come to the lecture on the examination of colour blindness, which gives the present extent of knowledge on the subject in a very lucid form, and with as much exhaustiveness as is attainable in a lecture. To the specialist the most interesting portion of the chapter is the author's description of his own chromatometer. He seeks to indicate the degree of colour-blindness by an exact estimation of the minimum quantity of coloured light necessary to produce in the patient the sensation of that colour, which minimum he expresses by a number. His apparatus is practically a Maxwell's rotating disc, the coloured surfaces of which are star-shaped, on a black ground, and divided into five zones, so that the inner zone shows a large coloured surface and very little black, and the outer zone very little colour and much black. The disc being rotated, each of the zones presents a given intensity of the test colour, and the top of the apparatus being covered by a lid, with an opening corresponding to each zone, it is easy to present to the patient a part of each zone, representing an exact graduation of colour from the centre to the periphery. In order that his apparatus may be observed under a constant degree of illumination, M. Landolt uses a simple photometer, consisting of a translucent card, on which is drawn a black line, which card is approached to the light until the black line is seen through the card by transmitted light, at which distance the chromatometer is then placed.

This subject is followed up in the succeeding chapter on "Indirect Vision," and an interesting and original account is given of an investigation into the relative chromatic sensitiveness of different parts of the retina, an inquiry which throws much light not only on the phenomena and the diagnosis of colour blindness, but on the physiology of the retina. The experiments were conducted by M. Landolt by means of a modification of Aubert's perimeter for examining the limits of the field of vision.

"It was for a long time thought (he says), and you will find it stated in many text-books on ophthalmology and physiological optics, that the periphery of the retina is achromatopic. They have even gone further, and founded on this supposition a theory of the physiology of the retina. Since in the parts nearer the macula the cones predominate, while they are almost completely wanting at the periphery, it was concluded, without hesitation, that the cones were designed for the perception of colours, while the rods were only charged with the quantitative perception of light."

In order to elucidate this point the author managed to present to each part of his retina successively the isolated colours of the solar spectrum, and found that all colours were recognised up to the extreme peripheral limit if only they were sufficiently illuminated and provided with a properly contrasted background.

"It results from this discovery that the supposed special function of the rods and cones has no existence, and that, in each examination of this character we should indicate exactly the nature of the light employed, its degree of saturation, its intensity, its size, as well as the character of the ground on which it appears, and the illumination of the room in which the experiment is made."

The result of his experiment on a large number of normal eyes is stated by M. Landolt in the following passage:—

"Starting from the periphery, blue is the colour which is first recognised; its visual field extends nearly up to the limit of the general visual field. After that comes bright yellow, which appears at first as white. Orange appears for a long time as yellow before it is recognised in its true tint.

"Red, which follows next in order, appears first as almost black, afterward as deep brown, brown, and finally as red. The field of green is still more limited than that of red. At the periphery it generally makes an impression of white or gray; nearer the centre bright green appears yellow; deep green as grayish-blue. It is only afterward that it is recognised as green.

---

(a) "Practical Examination of Eyes." By Prof. Landolt. Translated by Dr. Burnett. London: Baillière, Tindall, & Cox.

"Violet for a long while gives the impression of blue before it is distinguished as violet; its limits are the more extended the purer the shade.

. . . . . . . . . . . . .

"It is a great mistake to suppose that the perception of each colour throughout the whole extent of the retina is as vivid as at the centre. There is a great difference in the appearance of the same colour, according as it is viewed directly or at one side. The curves only indicate the limits of the visual field where the individual under examination gives the colour its true name, but it is then far from being pronounced. It only becomes of its deepest intensity in direct vision."

The remainder of this chapter deals with the relative sensitiveness of the different parts of the retinal area—*a*. For perception of light. *b*. For perception of colour. *c*. For visual acuteness. We are tempted to quote a few of M. Landolt's most instructive observations:—

"We would say that between the functions of direct and indirect vision there is no difference of kind, but only of degree, the eccentric parts of the retina having need to respond to excitations of the same nature of a greater quantity of the excitant. In other words, it is thought that the perception of light, the perception of colours, and the perception of forms, (visual acuteness) diminish in equal proportion, be it through a diminution of illumination, or a gradual removal of the object from the point of fixation."

"My experiments have proven that there is an essential difference between the functions of the centre and those of the eccentric portions of the retina. While the perception of light is nearly the same throughout the entire sensitive portion of the retina, the perception of colours is much less vivid in the eccentric portions than at the centre, and diminishes progressively in proportion as they approach the periphery of the visual field. The visual acuteness (perception of form) finally diminishes more rapidly toward the periphery than the perception of colours.

"Take, for example, my right eye, with all three functions at the centre = 1. The perception of light at a part 30° from the centre will be also = 1, the perception of colours = 1-14th, and the visual acuteness = 1-48th.

"Although these figures have only a relative value, the fact that of the three functions the perception of light remains the most constant, while the perception of colours and the visual acuteness diminish rapidly toward the periphery of the retina, the latter more than the former, is incontestably established by my experiments.

"The fact is of the greatest importance for the explanation of the different functions of the retina. It proves that these three functions are entirely distinct from each other and cannot be reduced to a single one, as we would be tempted to believe. On the contrary, we are justified in believing that there are different nervous elements, distributed in a different manner throughout the extent of the retina, presiding over the three different functions of the organ of vision."

This chapter is, on the whole, the most valuable in the book, and well deserves the perusal of the ophthalmologist. In connection with the diagnosis of retinal and neural diseases Mr. Landolt speaks of the perimeter as absolutely essential to diagnosis, and gives us very valuable suggestions as to its use in the differentiation of different forms of optic atrophy and neuritis, and of the hysteric hemianæsthesia which has recently been brought to light by Charcot. He tells us briefly of the restrictions in the colour field indicative of each of these affections, and speaks almost dogmatically of the prognoses which the observation of that field by the perimeter may enable us to make. Respecting hemiopia, he has an anatomical theory to which space forbids our referring, and maintains that there exists a crossing of the optic nerve fibres *behind* the chiasma, which may cause hemiopia in cerebral diseases which do not at all involve the decussation.

The author's first two chapters on the ophthalmoscope have special reference to the observations relatively of the upright and the inverted retinal images, and the differences therein in the various forms of ametropia. He lays great emphasis upon the necessity of determining the actual size of the details which we examine. He says—

"It is not a matter of indifference to know the real size of a foreign body which the ophthalmoscope shows us in the fundus of the eye. Neoplasms at the fundus or in the interior of the eye are likely to remain to us an unsolved mystery, if we do not take account of their real size; but it is especially for the purpose of studying the *topography* of the fundus that it is important to reduce the ophthalmoscopic image to its real size.

"It is of great importance to know what part of the eye we are examining; if such and such an affection of the fundus is found very near or very far from the macula; at how many millimetres from the papilla a foreign body is lodged, which we propose to extract. It will diminish considerably the chances of success of this operation, which, however, is sometimes successful, if we cannot put a just estimate upon the seat of the foreign body, such as can only be obtained by a knowledge of the real size of the ophthalmoscopic image.

"This question, however, is not one very easy of solution, and it cannot be solved without the assistance of mathematics."

Notwithstanding the high authority of M. Landolt I am not convinced that, for the purposes of ophthalmic practice, there is much to be gained by the exact measurement of fundus detail, however valuable those measurements may be for scientific investigations. In the case of intra-vitreous foreign bodies the estimation of exact size and position would be obviously useful, but in all fundus observations for practical purposes it is the relative position, size, and colour of retina lesions with which we are concerned, and these points can be as well estimated with an enlarged or diminished fundus as with one accurately measured, so long as the exact relative proportions are maintained. M. Landolt says as the result of his measurements, that—

"The relation of the size of the inverted image of an ametrope, under the circumstances mentioned, to that of the upright image, is, therefore—

"For *emmetropia* 1 : 55.
"For *hypermetropia* of 7.9 D 1 : 4.7.
"For *myopia* of 7.9 D 1 : 7.1.

"It follows from this that we should use the inverted image when we wish to take a general view of the background of the eye, while the upright image is to be employed when we wish to study it more in detail."

The next chapter deals with the determination of refraction by the ophthalmoscope, upon which method there is much to be said. It has recently become fashionable to depend to a great extent upon this method of testing ametropia and accommodation, and the optical market is glutted with ophthalmoscopes whose purpose is to combine with the ordinary mirror and convex lens a series of graduated lenses with which to balance the degree of hypermetropia or myopia of the patient.

With these instruments rough and ready calculations are made for spectacle adjustment, and eye surgeons are found talking with confidence of the observations made in this way as conclusive.

Upon the efficacy of such a method of determining refraction or accommodation I am wholly sceptical, and I am convinced that dependence on it vitiates the adjustments arrived at and injures the patient. It can give a hint to rhe observer and nothing more, for it admits into the calculation every error which can be produced by the peculiarities of refraction and accommodation of the observer himself. This M. Landolt fully admits, for he says:—

"You must not forget the one essential condition for determining the refraction: *the eye of the examiner, as well as that of the examinee, must have its accommodation completely relaxed.*

"If the examination is made in a dark chamber, and the examinee is told to look as if at objects in the distance, the accommodation is nearly alwysa completely relaxed. The proof of this is that the refraction, as determined by the ophthalmoscope, is nearly without exception less than that found by the usual means of test glasses, and nearly always corresponds with that found after the accommodation has been overcome by atropine.

"It is indispensable that the observer habituate himself to relax his accommodation during ophthalmoscope examinations. In order to do this emmetropes and hypermetropes must accustom themselves to look through convex lenses at objects situated at the focus of the lens, and to practise bringing their eyes to a condition of parallelism."

In a subsequent chapter will be found the following passage:—

"We have not, however, always command over our accommodation, since the ciliary muscle is not a muscle of the striated variety. But you will remember that the accommodation is in intimate relation with the convergence, and one is nearly always proportional to the other. Consequently, if we bring our eyes into a state of parallelism the convergence and accommodation are both abolished at the same time. Now, the muscles which preside over the direction of the eyes are under the control of the will, and we can easily gain a complete mastery over their movements."

At once we may say that we have no belief whatever in efficient voluntary or gymnastic relaxation of the accommodation, and we know of no method by which an observer can fit himself for calculating the refraction of patients by direct observation save by the constant use of atropine in at least one of his own eyes—a plan which no surgeon would think of adopting, and which, if adopted, would curtail his own powers of observation. The amplitude of accommodation of an average observer at thirty years of age is equivalent to 7.0. A judgment formed respecting the refractive condition of a patient solely by means of the ophthalmoscope is liable to error to this extreme extent. We know that we cannot entirely relax the accommodation without several days' constant use of atropine, and we have, therefore, great difficulty in believing that any amount of gymnastic practice will enable the observer to evolve from the calculation the influence of his own ciliary muscle or that any judgment of value as to the patient's refractive power can be obtained by such means.

Our analysis of M. Landolt's lectures being now completed, we have only to express a general opinion as to their merits, and we are able to speak with unreserved approval. The book contains within it as much as the average practitioner can expect to learn in reference to the examination of the eye and its media, and the information is given in a form at once intelligible and accurate—the hyper-scientific and algebraic garniture which is usual in such books being carefully avoided by the author. The translation is excellent, and, while here and there marked by the signs of its American origin, is free from the Frenchisms in which the lectures were written. Finally there is, as we have pointed out, sufficient originality within the book to make it worthy of reading by the specialist, and capable of instructing him, and we close its pages with the feeling that we have gained something by the perusal of it which its reviewing has necessitated.

## LANDOLT ON THE EYE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you do me the favour of inserting these few lines in your much-esteemed journal. I am sorry to find that the translation of my Manual of Examination of the Eye by Dr. Burnett contains some errors that I cannot allow to pass unnoticed, both for my readers' sake and for my own. I have therefore had an Appendix printed at my own expense, and have sent it to the editor, Dr. Brinton, who will be kind enough to deliver a copy to any former purchaser of my work who may desire one, and also to add it to as many of my books as he still has in his possession.

Allow me also to add that a Lesson on Ophthalmoscopic Enlargements, but of which the manuscript arrived in Philadelphia too late for publication, has just appeared in the first number for 1880 of the *British Medical Journal*.

I beg therefore those of my colleagues who have my work to apply for this Lesson as well as the Appendix, either to Messrs. Baillière, Tindall, and Cox, London, publishers of the English edition, or to me, 8 rue de la Bienfaisance, Paris.—I am, &c., DR. LANDOLT.

Paris, 1880.

◆

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns, were—in Calcutta 35, Bombay 37, Madras 35 ; Paris 40 ; Geneva 34 ; Brussels 36 ; Amsterdam 32, Rotterdam 30, The Hague 27 ; Copenhagen 29 ; Stockholm 23 ; Christiania 14 ; St. Petersburgh 51 ; Berlin 27, Hamburg 30, Dresden 22, Breslau 29, Vienna 27, Buda-Pesth 37 ; Rome 56, Naples 45 ; Alexandria 37 ; and New York 22 per 1,000 of the populations. Small-pox caused 70, and typhoid fever 102 deaths in Paris.

ACCORDING to official statistics Paris, Naples, St. Petersburgh and Rome are, at the present time the most unhealthy cities in Christendom. Paris shows a death-rate of 40, Naples 45, St. Petersburgh 51, and Rome 56 per 1,000 of the population.

## DOES THE GENERAL MEDICAL COUNCIL REPRESENT THE MEDICAL PROFESSION ?—IV.

OUR purpose in making the analysis of the General Medical Council, to which we have recently devoted our columns, was to show—and we think we have done so—that whatever the General Medical Council may be, it is not the embodiment of either professional or public interests—that its sole constitutional characteristic is a direct personal (and sometimes pecuniary) attachment to the licensing bodies, and its usual perceptible motive power, the desire to maintain a *status quo* which will be to the advantage of medical teachers and diploma-vending bodies. It is certainly not entitled to speak for the sick public, nor for the vast majority of the medical profession, nor for the Government of the country, and we, therefore, think that, in legislating for its reconstitution, it ought to be dealt with simply as a conclave of highly respectable advocates of the interests of diploma-giving bodies.

There may, perhaps, be some who will meet our complaint that the General Medical Council is not representative of the medical profession, with the reply that it is not intended to be so, but is created for the guardianship of medical affairs on behalf of the public and the State, and is not bound to express the views and interests o medical men, except so far as those interests are at one with the public weal. We believe we have seen this idea formulated in the *Times*, and it is worth notice, not because it is open to serious argument, but because it raises points worthy of thought. While we fully admit the right of the public and the State to an influential voice in the settlement of education, qualification, and registration of medical men, we insist upon the principle that our profession should be allowed to govern itself, and that no one has any right to interfere in the matter, as long as this self-government does not act to the public prejudice.

The education of barristers and solicitors is regulated by the Benchers, and by other bodies strictly within the control of their own profession; clergymen are qualified for their ministry according to a system regulated by clergymen and by Convocation, in which the outside public does not claim to interfere, and we know of no reason in public policy why medical affairs should be regulated by a conclave which is, through error in its constitution, not a medical self-governing tribunal at all. The State has a right to insist that none but competent practitioners should have charge of the public health, and, while it ensures this by its laws, it is bound to see that the education necessary for medical and surgical competency is afforded to the practitioner, and possessed by him. In all this, the interests of the profession and of the State are one and the same, and it is from the rank and file of the profession that the outcry for a full, sufficient, and honest medical education has come. But we contend that when the public interests have been cared for by legal restrictions upon medical practice which already exist, and by the vigilance of the representatives of the Crown in the General Medical Council, then the State has no further right or desire to interfere in the arrangement of medical affairs, and all matters relating to our profession ought to be absolutely within its own control.

The State has its voice in the work of the General Medical Council through the Crown nominees, and everyone admits the right of the public to exercise that influence, but the medical profession protests that while the Government is represented, while the vested interests of licensing bodies have overwhelming influence, while non-medical convocations and senates have considerable control, medical men themselves have no one to speak their minds. In considering the fairness of this complaint it must be remembered that there are many questions—altogether outside medical education—with which medical men are individually concerned. They are personally and very closely concerned in keeping up a fair educational and social standard of their profession, for while it may be temporarily convenient to the individual to be allowed ingress to the profession on cheap and easy terms, it is clearly to his disadvantage, once he has been admitted, that persons of inferior social position, and of obviously insufficient education, should be permitted to degrade his position as a gentleman and a man of scientific culture. For this reason the outcry of the profession has always been for the maintenance of such standard of education as would ensure that medical men should be gentlemen and know their business. In this very reasonable aspiration of our profession the General Medical Council, no doubt, participates, but it has failed to secure its realisation because the Council has not been animated—as earnest representatives of the profession would have been—with a firm determination to put a stop to the vending of cheap and easy diplomas at all hazards. Again it is the direct interest of the rank and file of the profession to stamp out the prevalent practice of medicine by unqualified persons—a system which is wholly illegal, and a defiant and contemptuous infraction of the law which the General Medical Council is is charged to administer, and which is, notwithstanding, tolerated (we might almost say patronised) by that Council. It is needless for us to give reasons for our contention that quack practice and the employment of unqualified persons as medical men ought to be prevented in the interest alike of the public and the profession. The Legislature was convinced of the necessity, and gave the power of prohibition into the hands of the Council, and it has not only not put those powers in action, but has adopted deliberately a policy of non-intervention. Now illegal practice is *the* question which most nearly touches the profession at large throughout England, for every day, and in every town in the kingdom, medical men are feeling the difficulty of holding up their heads as gentlemen, and making a living of their profession, in consequence of the competition of quacks, chemists, and unqualified assistants. Failing the relief which the Medical Council should give them, the general practitioners have been driven to institute prosecutions on their own behalf, and have therein received no aid and little countenance from the Council.

There cannot be a more convincing proof than this that the Medical Council has no sympathy with the medical profession at large. Had there been within it even one man who fully appreciated the daily work and the difficulties of the general medical practitioner, he would not have ceased to demand the enforcement of the law, or, if the law were insufficient, its amendment.

We have said enough to establish our case that the general medical practitioner ought to have, and has never had, a fair control in the administration of medical affairs. His right to that control was recognised in almost every one of the seven propositions of law which preceded the passing of the Medical Act, and it has its expression now in the Bills of Mr. Mills and of Dr. Lush which are before the House of Commons. It is demanded, on his behalf, that he shall elect his own advocate by his direct vote, and we have never heard a fair reason why he should not do so.

There is not, we believe, the least executive difficulty in the way of a plebiscite of the profession, and we believe that the result of that plebiscite would be the reinforcement of the Medical Council by a new class of members whose advice and experience is much needed in that body; but, in our opinion, the Medical Council would, after all, remain a badly constituted body unless a further reform of the elective system were made.

After much consideration of the question, we have arrived at the conclusion that to construct an efficient Council four changes in its construction will be necessary.

1. To reduce the number of representatives of licensing bodies by disfranchising peremptorily those bodies which have no considerable share in medical education or qualifi-

cation, and no special function as qualifying bodies to fulfil; *e.g.*, the Apothecaries' Companies of London and Dublin, and the University of Durham.

2. To cause the Crown nomination to be exercised in favour of distinguished working practitioners rather than exalted metropolitan doctor-princes.

3. To add to the Council a fair proportion of representatives directly elected by the rank and file of the profession.

4. To transfer the election of the representatives from the executive body to the voting members of the body corporate of each licensing body.

The subject is a large one, and many reasons might be adduced for these changes, but the necessity for reconstruction is everywhere admitted, and if we can be considered to have established the necessity for direct representation of the general medical practitioner, we neep not delay to discuss the details.

◆

## PAYING PATIENTS IN HOSPITALS.

THE increasing demand for hospital accommodation and treatment on behalf of the middle and upper classes, has in late years been a prominent subject of debate. That there exists a real necessity for some arrangement whereby the privileges enjoyed by the legitimate recipient of the aid the hospital charities afford may be offered to those who are ineligible to receive them, has become a recognised fact; and there is little to be done now in enforcing its truth. Attention is rather confined to the consideration how best that arrangement can be made, that it shall not on the one hand rob the proper objects of charity, or, on the other, interfere with professional rights. Too much, we cannot help thinking, has been heard in relation to this latter point, and those who have constituted themselves censors of each scheme as proposed, have been entirely forgetful of the elements which guide the call for skilled labour, whether in the medical or in any other profession.

The present position held by the advocates of the system of pay hospitals is admirably explained in a work recently published, (*a*) in which a detailed account of the attempts made to establish such institutions is presented to the reader, as well as an analysis of the results obtained through the adoption of schemes for the admission of paying patients in ordinary wards. Mr. Burdett's inquiries extend to all countries, and the information he has collected is not alone interesting, but is an important assistant in helping to the formation of a conclusion respecting the feasibility of establishing a commercially successful system of paying hospitals in this country. We are, however, concerned at the moment with the admission of patients of the paying class into the wards of hospitals that exist solely as charities at present. Since the publication of Mr. Burdett's work the governing body of St. Thomas's Hospital have submitted a scheme with this object in view to the Charity Commissioners, a former proposal to the same effect having been negatived by the House Committee. By the arrangement suggested in the latter plan, two classes of patients will be received. One set will occupy the rooms of the hitherto unused pavilion of St. Thomas's Hospital; the second class will be distributed among the ordinary free patients, and will pay a less amount than those occupying the special wards. The question that arises to disturb the calculations of the reformers, is the very essential one of medical attendance. Are the patients to be entirely dependent on the regular staff of the institution, or shall they be allowed liberty of choice in the selection of their adviser? This is a vital consideration, and may be expected to influence the problem very seriously. At first sight it might seem manifestly unfair that the services of any but the regularly-appointed officials should be invoked on the immediate spot of their gratuitous labours by such patients as are prepared to pay the regular charges for attendance. It is expressly to be understood that the sum paid for the accommodation of the special wards, shall be inclusive only of nursing and diet, and that the cost of actual medical attendance beyond that given by a salaried resident medical officer, whose duties will be merely of general supervision, shall be defrayed by the patient, and be subject to private arrangement between himself and the practitioner he selects to attend him. With this proviso, it would be as unjust to the patient, to confine his choice to the limited number of practitioners on the hospital staff; and it is surely not for them to object if the choice made should not be in their favour. No scheme that does not provide for the absolutely unhampered freedom on the part of the patient can ever work satisfactorily; moreover any objection to this plan will be dictated by a spirit of unwisdom highly detrimental to the success of the endeavours that are being made to meet a declared want.

Somewhat different is it with regard to the less opulent patients, who will become occupants of the general beds of a hospital. With them it will be a question how to get well at a small expense. But even in their case, any desire to obtain other advice than that tendered by the physician or surgeon under whom they are admitted, should be encouraged as freely as the wishes of the better-class invalids. There is no question of the ability of one man as compared with another, involved in these considerations. We are led to them solely in the interest of the movement that is taking place, and under the conviction that benefit will result to an extent commensurate with the necessity for it, if the regulations are framed with no other restrictions than those connected with proper ward management.

The Home Hospitals Association occupies a position of its own. It undertakes to provide those who will pay for it with the comforts of home and the advantages of hospital *régime*, at a reasonable rate of payment; and further undertakes to carry out on the patient's behalf, the directions of the medical man who has been called to attend his case, when other aid than that offered by the resident officer is sought. The boon that will be conferred on the middle classes by such an hospital can scarcely be overrated. The multitudinous instances of sickness, under the most unfavourable conditions, in chambers, in lodgings, &c., &c., are proof enough that a central refuge, with certainty of skilled nursing and properly prepared food, is likely to supply a sorely-felt want. It is, therefore, satisfactory to know that the efforts of the Society of which Mr. Burdett is secretary have at length overcome its worst difficulty; and, in spite of judge's orders and prejudiced

---

(*a*) "Pay Hospitals and Paying Wards throughout the World." By C. Burdett, Hon. Sec. Home Hospitals Association, London: J. & A. Churchill. 1879.

misconception, it has succeeded in establishing its quarters in what bids fair to be a fitting sanatorium. We cordially wish success to the movement and to any plan which has for an object the improved treatment of illnesses. But due care must, nevertheless, be had, that in eagerness to extend the advantages of hospitals to patients not contemplated by the benefactors thereof, the class for whom they were originally intended do not in any way suffer by the innovation. It has been urged that the increased income derived from this source would benefit the poor by enabling larger buildings to be erected from the funds accumulated by this means; but it must not be forgotten that while these sums are growing, beds are being filled, possibly to the exclusion of indigent sick, to whom delay in reception and treatment means death. With the proposal to utilise the unemployed pavilion at St. Thomas's, no fault can be found, that is supposing always that the use of it by patients is associated with no conditions binding them to select certain practitioners to attend them.

There is, undoubtedly, need of reform in the direction indicated in Mr. Burdett's volume, and the evidence he adduces that the changes he recommends have been followed in other countries with so large a measure of success ought to be inducement enough to lead to the adoption of similar measures with us.

## PATHOLOGICAL FOG.

The term "fog" is applied by the agriculturists of the North to the after-math, or growth of herbage, that comes in autumn when the hay-harvest is over, and so under the title of "pathological fog" we desire to call attention to an after-growth of disease that may be looked for when the present luxuriant crop of respiratory affections has been disposed of. The returns of the Registrar-General show that the mortality in London for the week ending Saturday, February 7th, was higher than it had been for forty years, amounting to 48·1 per 1,000 of the estimated population, and that the enormous excess of the death rate over the average of previous years and over that of provincial large towns was attributable mainly to diseases of the respiratory system. These diseases caused 1,557 deaths in the week referred to, that is to say, 1,118 above the corrected average. But the deaths from respiratory diseases afford but a slender indication of their prevalence. It is the old and feeble who principally succumb to them, their immediate lethal effects being proportionate to the ages of the persons attacked by them, and for every individual who dies of bronchitis, ten, twenty, or a hundred individuals may have suffered from it. Until we have registration of disease as well as of death, we shall be unable to estimate, with any approach to accuracy, the relation subsisting between mortality and prevalence in any particular disease at different seasons and ages and under different social conditions. Experience in churches, schools, and public institutions during our recent dismal weather might have led to the belief that the rate of mortality from respiratory diseases then recorded corresponded with the universal prevalence of respiratory troubles. Everywhere were heard choruses of coughing and in private practice medical men were not unaccustomed to find whole households prostrated by catarrh. The severity of the weather has now been mitigated, and the damp carbonaceous fogs which were the chief source of discomfort and danger, no longer encompass us; so we may expect that the excessive mortality which reached its climax a fortnight ago will diminish rapidly, and that respiratory diseases will sink nearly to their normal level in our bills of mortality. But long after this has happened we shall have reason to remember these fogs as causes of disability and death. For it can scarcely be doubted that the irritation of the air passages which they have occasioned, or the pneumonic processes or pleuritic exudations which they have set up, will in many persons result in the consolidation and destruction of lung tissue which form the anatomical basis of consumption. Chiefly among the destitute and badly-nourished will such consequences ensue; but even the rich and well-fed will not be exempt from them, especially when proper treatment and precautions are not observed. It cannot be too strongly insisted on at a time like the present that no cold is too trifling to deserve attention, and that neglected colds are the great feeders of phthisis in all ranks of society. And phthisis will probably form the principal and most calamitous constituent of the pathological fog which we predict as an after-growth of the immediate pathological consequences of the weather through which we have just passed. It will not, however, stand alone. Bronchitis, emphysema, laryngeal affections, and a long train of kindred evils, have received an impetus which will be felt for years to come. And besides these, various constitutional diseases which it is more difficult to connect with climatic conditions have also been stirred up. Many an invalid of the next decennium will have to date his invalidism from January or February, 1880.

# Notes on Current Topics.

## Proof of Death.

Those timid beings who are haunted by apprehensions of being buried alive, and who make testamentary provisions against such a contingency, may now take courage, for science has supplied an infallible means of determining whether or not the vital spark has quitted the mortal frame. Electricity enables us to distinguish with absolute certainty between life and death; for two or three hours after the stoppage of the heart, the whole of the muscles of the body have completely lost their electric excitability. When stimulated by electricity they no longer contract. If, then, when Faradism is applied to the muscles of the limbs and trunk, say five or six hours after supposed death, there be no contractile response, it may be certified with certainty that death has taken place, for no faint, nor trance, nor coma, however deep, can prevent the manifestation of electric muscular contractility. Here there is no possibility of mistake, as there certainly was when the old tests were employed. Muscular contractility under the Faradic stimulus disappears gradually after death. It is instantly diminished, but only finally extinguished in about three hours; and hence Dr. Hughes Bennett has suggested that electricity may sometimes be of use in medico-legal investigations, by affording evidence as to the time of death.

### Dr. Richardson's Legacy.

DR. RICHARDSON has, it is reported, finally decided on the use to be made of the wine left him by the late Sir Walter Trevelyan. The terms of the bequest were somewhat binding in their nature, requiring that the gift should be devoted to the interests of science. All natural channels for disposing of the liquors were thus closed to the legatee, and his acquisition consequently had much of the cumbrous inutility popularly associated with a "white elephant." Acting on the suggestions made to him, however, Dr. Richardson has resolved to yield up the wines for the purposes of chemical investigation, the object in view being to determine the exact nature of the substances on which the varying flavour of different wines is dependent. The inquiry will be likely to yield some good results, and Dr. Richardson may be congratulated on the benefits likely to follow from his decision.

### The London Fever Hospital.

THE fact that the Fever Hospital in the Liverpool Road, Islington, is the only place available within an immense area for the reception of infectious diseases, ought to be sufficient to insure the adequate support of so necessary an institution. We are sorry to learn, however, that the funded property of the hospital is being steadily drawn upon to meet current expenses, the explanation being readily enough given that the depressed state of trade in recent years has perceptibly affected the amount of the annual subscriptions. That this should be the case is not astonishing, but considering the essential nature of the part played by the fever hospital in the treatment of disease, and recognising that it affords an asylum to sick persons who could not be admitted into the wards of a general hospital, the special claims it has on the charitable ought to be immediately responded to. The small proportionate income received from transfer and other paid-for cases, does not serve appreciably to diminish the annual deficit; and some steps need to be taken early, to prevent the serious crippling of the hospital's resources. We had not long since a striking example in the east of London, of the evils which follow a prolonged course of "dipping" into vested capital. It is to be hoped that we may not hear of like possible evils occurring to the institution in the northern district. It may be added that last year 908 patients were treated in the hospital, besides 123 drafted from other places to it.

### The Royal College of Physicians of London Examinations.

THE Royal College of Physicians of London has formally adopted a revised series of regulations to be observed by candidates for its licence. It will require these to pass *three* examinations, the first being open to any duly registered medical student. The subjects included in it are osteology, chemistry, with chemical physics, materia medica, medical botany, and pharmacy. Certificates of attendance on lectures will not be demanded; but before entry to the second examination in anatomy and physiology, with practical physiology, proof of attendance on hospital courses in these subjects must be produced. The third examination may not be entered for until two years subsequent to passing the second, and includes medicine, surgery, and midwifery, and papers will be further set on forensic medicine, therapeutics, and public health. Proof must be given of practical clinical instruction in medicine, obstetrics, and surgery. The changes will most probably be productive of beneficial reform in clinical teaching, but it may be, not without reason, objected that the provision necessitating the expiry of two years from the time of passing examination number two, ere presenting for number three, is calculated to work ill in practice. The actual time spent on hospital attendance is little enough when limited to four years, but many men cannot afford to give more than this. Should they chance to be referred for a period on attempting the second examination, no matter how well they may know the elements of medicine and surgery, they will perforce be hindered from qualifying at the usual time. The answer will probably be that no man can rightly appreciate the facts of surgery until he has passed his primary examination in anatomy; but this is a narrow view that is not authorised by fact. Though the College of Physicians is wise in leading the way in the direction of reform, it acts injudiciously in thus paralysing the efforts of the many who seek to fit themselves to begin responsible education at an early date, by entering on hospital appointments.

### The "Call" to Dr. Farquharson.

AN influential body of the electors of West Aberdeenshire have invited Dr. Robert Farquharson to contest that seat in the Liberal interest at the approaching general election. Dr. Farquharson's eminent qualities render it highly desirable that he should be able to advance the cause of public hygiene in the "House" by lending his aid in discussing important public measures. Dr. Farquharson has made himself an undoubted authority in matters of sanitation, and his presence in Parliament would do much to advance the great cause of hygienic reform. The hearty wishes of the medical profession will follow him in his candidature.

### French Views of Syphilis.

A FRENCH journal, *L'Année Médicale*, of Caen, has, in its last few issues, had some excellent lectures on syphilis by Dr. Denis-Dumont, surgeon-in-chief of the Hôtel Dieu of that city. In concluding his last one, he says:—"These three conclusions contain the result of our study of syphilis—a *unity* of origin of all syphilitic maladies; the *incurability* of the disease, when the immense variety of its effects is considered; and as a logical consequence an indefinite *continuance* of treatment, with occasional interruptions."

These discouraging views, we believe, are those now generally prevalent in France. They are forced upon surgeons by constant discoveries of hitherto unobserved connections of pathological changes with previous syphilitic poisoning; and probably those discoveries are by no means complete.

### Hydrofluoric Acid Inhalations in Diphtheria.

HENRI BERGERON has read a paper before the Société de Médecine on the above method of treating diphtheria. He has tried it in twenty-four cases, out of which seventeen were severe, and he has had five deaths, four of thes being infants. The dose he has found suitable is one gram for each cubic metre which the apartment contains, evaporated in the space of three hours. He claims (1) that the inhalations thus given have never produced injurious results. (2) All who had been submitted to this treatment for forty-eight hours were cured. (3) The false membranes do not persist beyond the fifth day. (4) In no case has he observed paralysis supervene in the soft palate or elsewhere. (5) No case of contagion has occurred among the attendants or the household.

### A Simple Method of Evacuating Small Calculi.

Dr. Mercier recently demonstrated before the Société de Médecine of Paris an easy and practical means of getting rid of small vesical calculi. It consists in making the patient lie on his belly; then the calculi fall by their own weight into the anterior part of the bladder. The patient is then allowed to rise slowly on to all fours. He micturates in this position, and the calculi, which have not yet had time to return into the *cul-de-sac* behind the prostate, are carried away in the stream of urine.

### Treatment of Prolapse of the Rectum by Hypodermic Injection of Ergotine.

M. Vidal read a paper on this subject at a recent meeting of the Paris Academy of Medicine. He said that prolapse of the rectum may be cured easily and in a comparatively short space of time by means of hypodermic injections of a solution of the extract of ergot known as ergotine. By this new method M. Vidal had succeeded in curing three adults whose cases were given in detail. He employed a solution of one gramme of extract of ergot or ergotine of Bonjeau in five grammes of aqua laurocerasi. Each injection consisted of fifteen or twenty drops (exceptionally twenty-five), which is equivalent to twenty to twenty-five centigrammes of ergotine, otherwise of the extract of one and a-half gramme to three grammes of ergot of rye. None of the injections were followed by any inflammation or abscess. Bonjeau's ergotine causes some pain; Zern's solution is better tolerated.

### Subcutaneous Emphysema during Parturition.

Dr. Peper narrates the case of a woman, æt. 24, primipara, who had a prolonged labour which had to be terminated by forceps (*Le Pratceien*, Feb. 9). During the operation there was produced a swelling of the skin above the right clavicle, increasing with each effort. The swelling extended to the neck, to the face, and to the upper part of the thorax, and there was manifest crepitation. The respiration was more feeble in the right than in the left lung. Resolution of the emphysema occurred in twelve days. The author explains it by supposing that there was rupture of some of the pulmonary vessels, and passage of the air by the bronchi into the mediastinum and subcutaneous cellular tissue.

### Production and Increase of Secretion of Milk by the Ricinus communis.

MM. Boucher and Foussagrives have established the efficaciousness of this method of increasing or re-establishing the secretion of milk. It is used thus:—A handful of the leaves of the Ricinus communis are boiled in a litre of water; the breasts are bathed with this decoction for fifteen or twenty minutes; there is then applied to the nipples a poultice made with a part of the same leaves, and they are left on till they have become dry. The result is obtained after a few hours; but if the secretion is very tardy we may add to this the employment of fumigations of the boiled leaves directed to the genital organs.

### Curious Death from Gas.

An inquest was held on the 14th inst. at Liverpool, on a girl—Isabella Atkinson—who was found dead in bed at the Shaftesbury Temperance Hotel. The waitress took her to her bedroom at eleven o'clock at night, and left her with the gas burning. Next morning the boots knocked, and receiving no answer, looked in, and found her lying on her side in bed dead. There was a strong smell of gas in the room, and the gas-tap was full on. The jury found that she had died from the effects of inhaling gas when asleep; "but how the gas came to be on at the time—whether by being imperfectly turned off by deceased, or by going out from any cause through the night—the evidence did not sufficiently show." We think they need not have felt any difficulty as to how the gas was "full on." The girl came from the Westmoreland hills and obviously knew nothing about gas, and blew the flame out as she would blow out a candle. The smell of the gas would not alarm her any more than the smell of a smouldering wick; and in all probability her thoughts were engaged in other matters, and, being tired, she quickly fell asleep.

### The late Dr. O'Leary, M.P.

A medical contemporary says that Dr. O'Leary, whose untimely death we have to regret, travelled from Ireland to London last Sunday fortnight, without having taken the precaution of providing sufficient wraps for the time of year. He caught a chill on the journey, and was so unwell on his arrival in London on the Monday, that he got into bed in his clothes in order to get warm. He went about during the week with more or less difficulty until Friday, when he was obliged to take to his bed. Dr. Hawksley, who saw him late on the evening of that day, found his temperature at 103° Fahr., his pulse 140, and his breathing laboured and rough. There was evidence of considerable renal congestion. Next day, Dr. Hawkesley invited Sir William Gull to see him; he was then much worse, and the symptoms of pneumonia more pronounced. He was slightly delirious on the Saturday; and in spite of the unceasing attention of Dr. Hawksley and Mr. Tegart, he expired at 1.30 p.m. on Sunday week. The chill he had caught had evidently extended to the excretory organs as well as the lungs, and had no small share in the unfortunate result.

Dr. John T. Banks has been appointed Governor of the House of Industry Government Hospitals, Dublin, *vice* Sir D. Corrigan, Bart., M.D., deceased.

## How to Gargle the Throat.

Dr. Lowenberg, whose contributions on "Adenoid Tumours of the Naso-Pharynx" to our columns last year attracted attention, recommends the following method of gargling the naso-pharyngeal cavity. The patient inclines the head horizontally backward, and performs movements which we may call "quasi-deglutition," not including the last portion of this physiological action, definite swallowing. The liquid is passed much higher behind the soft palate than the ordinary method of gargling will permit. Some persons succeed so well in this manœuvre that they are able to eject by the nose the liquid which has been received by the mouth. Moreover, these rapid muscular contractions completely detach the abnormal secretions, which can then be easily expelled, and the greatest possible relief is thus given to the patient. Another method is to fill the mouth with the tongue; this confines the gargle to the pharynx. The head should then be bowed in a forward direction until the top of the cranium is its lowest portion. In this position the gargle will not only wash the roof of the pharynx—giving a sort of sitz-bath, as it were—but if the patient have caught the trick, will flow forward through the nose.

## Amateur Vaccination.

At the Newry Union last week, the relieving officer reported that a Mrs. M'Cann had refused to allow a doctor to vaccinate her child, and had performed that operation herself. She had herself taken the lymph from some other child.

Under the heading of "Deaths" in our present number, will be found the name of a member of our profession who has reached the patriarchal age of 95. The deceased, Mr. Tribe, of Rochester, obtained his diploma of M.R.C.S.E. sixty-seven years ago.

It is reported from Dunmanway, co. Cork, that a young man and young woman, son and daughter of a farmer living near that town, while sitting near the fireplace in their own house, during the prevalence of a violent storm, were struck by lightning, and killed on the spot.

The yellow fever epidemic has again made its appearance at Rio Janeiro, the deaths within the city numbering from eight to ten daily. In consequence of much sickness prevailing among the shipping in the port the vessels have been removed from the shore and dispersed through the harbour.

The death-rate in the principal large towns in the United Kingdom from the seven principal zymotic diseases ranged last week from 0·6 in Portsmouth and Leicester, to 6·3, 6·9. and 7·6 in Plymouth, Nottingham, and Dublin. Whooping-cough showed the largest proportional fatality in Salford, Newcastle-upon-Tyne, and London; measles in Nottingham and Hull; and scarlet fever in Sunderland, Bradford, Dublin, and Bristol. Enteric fever is prevalent in Sheffield; 10 fatal cases were registered there last week, of which 7 occurred in the workhouse. Small-pox caused 12 more deaths in London, and 3 in Dublin, but none elsewhere.

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Glasgow Science Lectures.—On the night of Thursday, the 19th inst., the penultimate of the season, under the auspices of the Glasgow Science Lecture Association, was delivered in the City Hall by the Rev. W. H. Dallinger. Dr. Fergus presided, and there was a very good attendance. The subject of the lecture was "The Latest Researches into the Origin and Development of the Least and Lowest Forms of Life;" and the lecturer at the outset declared himself a firm believer in the doctrine of evolution. At the same time, he said that nothing had yet been ascertained to warrant the conclusion that the not living was without the intervention of living things, changed into that which lives. He further pointed out that Professor Huxley had shown that spontaneous generation was not required by the doctrine of evolution, and proceeded to give an account of his own researches tnto the very lowest forms of animal life. He illustrated the magnifying power of the lenses he employed by throwing on a screen by means of a magic lantern the sting of a wasp and the point of a needle, and then he described and illustrated in a similar manner the life history of two monads, as observed by himself and Dr. Drysdale, of Liverpool, who assisted him in conducting his researches. The result of the whole fully established that these, the least of organic forms, multiplied by fission and self-division, and ultimately by means of germs or eggs. Goiug thus down to the very fringe and margin of organised existence, he found that the method was precisely the same as in the highest ranks, which multiplied finally by genetic processes, by parental products. The question still remained—did the minute germs which he discovered, germs so small that they were, except in mass, invisible even under the most powerful instruments—have a power of heat resistance greater than was possessed even by adult forms? By a series of investigations he arrived at the conclusion coincident with other biologists, that the adults were killed at a heat of 140 deg. Fahr.; that the spores or eggs of one of the forms brought forth young at 180 deg.; that two of the forms required a temperature of 250 deg. to destroy them; that other two required a heat of 260 deg.; and that another required a heat of 300 deg. Fahr., before the germ was destroyed. And this latter form, he further showed, was the very form on which Dr. Bastian's latest experiments were made, which he had put forward as proving the theory of spontaneous generation. Dr. Bastian found that life reappeared after the organism had been subjected to a heat of 270 deg. Fahr., and therefore, he argued, it must have arisen *de novo*, whereas the lecturer's experiments had proved that the germs could only be killed at a temperature of 300 deg., or 30 deg. higher than the temperature to which Dr. Bastian exposed his infusions.

Philosophical Society of Glasgow.—Sewage and sewer gas form a subject which has been professionally piped, not always very philosophically, almost *ad nauseam*, in Glasgow. At a meeting of the Glasgow Philosophical (!) Society, held on the 18th inst., Dr. Fergus, as was meet, in the chair, Dr. Neil Carmichael furnished a contribution to the subject. "The Trap and Water-Closet System," was the subject of Dr. Carmichael's paper. This gentleman explained in the course of his remarks that for a considerable period he has been making experimental investigations into the trap and water-closet system, and the relations of the same to sewage products, gaseous and other; and as a result he had come to the conclusion that germs and other substances injurious to health did not pass through a sound water trap. Clearly, then, he said, they must look to other sources for the contaminations of the atmosphere, which were frequently found to prevail in houses, and which proved so serious and injurious to health. He had ascertained from experiments that an opening made by a small pin in the soil pipe was sufficient to admit particles into a house that were dangerous to health and likely to spread disease, and when they considered how imperfect some of these pipes were in many respects, it was no difficult matter to account for the presence of noxious gases in dwellings. While he admitted that the water-closets in general use, where the traps were perfect, were not so objectionable as some people were disposed to assert, still there belonged to them the serious objection that between the pan and the trap there was a portion of soil pipe which was never or rarely free from objectionable matter, and therefore was a fertile source of annoyance and danger. He thought an effort should be made in the water-closets of the future to get rid of this objectionable feature. Dr. Carmichael exhibited a diagram of an improved water-closet, and received a vote of thanks for his paper.

**DEATH FROM HYDROPHOBIA AT NEWMILNS, AYRSHIRE.**—Assuming the correctness of diagnosis, deaths from hydrophobia are surely becoming alarmingly prevalent. A death from this cause is reported to have occurred on the 19th inst. at Newmilns. A young lad, fifteen years of age, son of Mr. Thomas Donald, Crosstree, about the end of December last, received a bite from a strayed collie. The wound healed up at the time, and the lad was to all appearance quite well up to Monday the 16th inst., when he was seized with vomiting, and soon afterwards unmistakeable symptoms of hydrophobia were exhibited. He died in all the agonies of this terrible malady. The dog is believed to be still at large.

**DEATH OF DR. JOHN WILSON, OF INVERNESS.**—Dr. John Wilson, Inverness, one of the leading medical practitioners in the North of Scotland, died suddenly in Edinburgh (where he had gone on a visit) early on the morning of the 17th inst. Dr. Wilson was a son of the late Provost Wilson, of Nairn, and took his degree of M.A. at Aberdeen. He graduated M.D. at Edinburgh in 1842, and in the same year took the L.R.C.S. Edin. In 1866 he was elected a F.R.C.S. Edin. Immediately after graduating he was appointed house-surgeon of the Northern Infirmary, at Inverness, and after entering into private practice he was appointed one of the honorary consulting physicians, month after month, for over thirtyyears, earnestly and assiduously aiding with his skill and experience the resident medical attendant. Dr. Wilson, notwithstanding his having a wide and extensive range of patients among the more opulent classes of society, was ever ready to the call of duty from the very poorest. Wherever pain had to be relieved he was ever ready to go without fee or reward, and the excessive fatigue he thus underwent in the course of an otherwise extensive practice, undermined his constitution. He died in the sixtieth year of his life. Among the appointments he held were Medical Officer of the Inverness Prison, Consulting Physician to the Northern Counties District Asylum, and Surgeon of the Inverness Artillery Volunteers.

**REGISTRAR-GENERAL'S RETURNS.**—According to the return of births, deaths, and marriages for the week ending with Saturday, the 14th inst., the death-rate in the eight principal towns was 22·2 per 1,000 of the estimated population. This rate is 3·4 per 1,000 under the rate for the corresponding week of last year, and 0·6 under that for the previous week of the present year. The lowest mortality was recorded in Edinburgh, viz., 19·0, and the highest in Perth, viz., 42·9. The mortality from the seven most familiar zymotic diseases was at the rate of 3·1 per 1,000, being 0·8 less than during the previous week. Whooping-cough still continues the most prevalent of these diseases, although there is a decrease of fifteen in the number of deaths from that disease recorded last week. Two deaths recorded in Dundee were due to the Tay Bridge accident. The number of deaths from inflammatory affections of the respiratory organs was 33 less than that registered during last week. The mean temperature was 39·3, being 5·8 below that of the week immediately preceding, and 3·2 above that of the corresponding week of 1879.

**DEATH OF DR. GEORGE DALLAS BAIRD, F.R.C.S. ED.**—This much-esteemed and worthy member of our profession died at his residence in Linlithgow on the night of Tuesday, the 17th inst., at the mature age of 75. Dr. Baird was born in Linlithgow, and has been in practice in Linlithgow and neighbourhood for the last half century. From his many excellent qualities he was much esteemed by all who knew him, and especially by the poor in the district; for his kindly consideration for their necessities he was regarded with a feeling of grateful affection. He was widely consulted on all professional subjects.

**HEALTH OF EDINBURGH.**—For the week ending with Saturday, the 14th inst., the mortality in Edinburgh was 81, and the death-rate 19 per 1,000. Eight deaths constituted the zymotic mortality. The solitary death from fever occurred in the new town.

◆

## Literary Notes and Gossip.

IT is announced in literary circles, that Her Majesty will create Mr. Theodore Martin a K.C.B., in acknowledgment of the manner in which he has performed the task of writing the Prince Consort's "Life."

⁂

AN extraordinary prize of 3,000 francs has been awarded by the French Academie des Sciences to Mr. Crookes, F.R.S., editor of the *Chemical News*, in recognition of his recent discoveries in Molecular Physics and Radiant Matter.

⁂

THE Anatomical and Surgical Society of New York has commenced a monthly publication of the papers read before it. The annals will be edited by Dr. Charles Jewett, and published by G. P. Putnamo's Sons, New York City. The first number is well printed and has several readable papers.

⁂

THE International Literary Association, which has been established about eighteen months, and to which several known writers in the medical profession belong, announce a series of "Literary Afternoons" in London during the present season. The first was held on Monday last, and was a most enjoyable one, although not so well patronised as it deserved. Mr. Jenkins, M.P. occupied the "Afternoon" with readings from some favourite authors.

⁂

WE have received two monographs on the "Heart" during the past week—one by the President of the Medical Society of London, Dr. Cockle, entitled "Contributions to Cardiac Pathology," the other, by Dr. Henry Kennedy, of Dublin, entitled "Observations on Fatty Heart." Both writers are well known to the readers of the *Medical Press.* We shall take an early opportunity of commenting upon their productions in book form.

⁂

THE lxxx. volume of Braithwaite's "Retrospect," recently issued, well maintains the character of the work as a useful and complete *résumé* of the advances made in medicine and surgery in the past half-year. Several communications made to our own columns are embodied in the work, and its contents include abstracts of the most important papers and essays read before the societies, and contributed to the pages of contemporary journals.

⁂

MESSRS. WOOD & Co., the well-known publishers of New York, announce a practical treatise on "Neurasthenia: its Symptoms, Nature, Sequences and Treatment." By George M. Beard, A.M., M.D., of New York. The treatise is one on which Dr. Beard has been specially engaged for a number of years, and it will be devoted mainly to his original observations and researches on this important and growing subject. It is expected to be ready next month.

⁂

COMMENTING upon the views entertained by different sections of the profession, upon the propriety or utility of contributions in non-medical literature, an American contemporary finds in the increasing number of popular articles on medical and allied subjects, an evidence that the scientific standing of medicine is rising in the general opinion of mankind, as it is *in fact.* The position of the physician has been said to be the measure of a nation's civilisation. It is certain that with the increased intelligence of a people more will be demanded of the medical man, and this demand, history shows, has always been responded to.

⁂

The title of "Practitioner" is becoming very popular for medical journals. There is the *Practitioner* published in London; *Le Praticien* published in Paris, the *American Practitioner* of Louisville; the *Country Practitioner* of New Jersey; and still another, *The Practitioner* of Baltimore, the first number of which is now before us. The new candidate for professional favour, is bright as most new things are, and we wish it the success its editors so confidently predict; but if gentlemen with literary aspirations cannot coin something fresh in the way of titles for their mushrooms, the *Index Medicus* will become muddled.

⁂

PART 42 of Messrs. Bentley and Trimen's exhaustive work on "Medicinal Plants," completes one of the most important of recent publications. The serial issue of the volumes has kept the work prominently before the notice of subscribers; but we doubt if the greater number of medical men know the excellence and beauty of these plates. The publishers, Messrs. J. and A. Churchill, have included in the final number, just received, a double index, one arranged in systematic order, the other a general table. The preface, and a number of corrections and additions, are likewise included. We shall notice the completed work at a later date.

⁂

MESSRS. LETTS, SONS, & CO., the well-known publishers of some excellent Medical Diaries, Medical Account Books, &c., are issuing in monthly instalments, maps of the whole world at the price of sevenpence each part. Taking into account that these maps are printed in colours, size 17 × 14 inches, with the latest geographical and territorial discoveries and alterations, and that each part contains three maps, the venture is a fair specimen of this go-a head age, and should command a speedy sale. Of course the number of maps will be too large for mounting to hang in any ordinary size library, and to obviate what might prove deterrent to some who wish to purchase the entire series, the publishers have provided a neat case to contain them.

⁂

A PAMPHLET on "Climate and Health in South Africa," by Mr. James Bonwick, F.R.G.S., published by Messrs. S. W. Silver and Co., contains a vast amount of valuable information, likely to be of great value to intending colonists. With forty years' experience of the country, Mr. Bonwick speaks authoritatively, and his dictum is eminently favourable to the climate in Africa. He takes the various districts in turn, and exhaustively considers the advantages and disadvantages attendant on a residence at each. We commend the work to all who are interested in our Cape colonies, and to intending emigrants it will prove a most invaluable help in aiding them to arrive at conclusions respecting the land in the South.

⁂

THE North-Western Association of Medical Officers of Health have issued their volume of "Proceedings" for the year ending February, 1879. It indicates that the Society is in a satisfactory condition, and that it is accomplishing some good and useful work. At the quarterly meetings held during the year, papers of considerable interest were read, abstracts of which are contained in the "Proceedings." One of these, on the "Registration of Disease," communicated to an extraordinary meeting of the North-Western, Northern Counties, and Yorkshire Associations, is particularly interesting; and much value attaches, too, to Mr. Vacher's paper (p. 10) on "The Diseases of Animals rendering them unfit for the Food of Man." The other papers are, an excellent one by Dr. Vernon, on "Birth-Rates, Death-Rates, and Estimates of Population," and one by Mr. R. McNicholl on "Hard-Water." A noteworthy feature is afforded by abstract reports of discussions which occurred on these papers.

⁂

PAMPHLETS.—The following have been received since the publication of our last list:—"Responsibility restricted by Insane Delusion," by Drs. Wright and Bellefontaine. "Hints on the Antiseptic Management of Wounds," by F. M. Caird, M.B. "The Family Physician," Part I. "On Antiseptic Surgery," by John Bishop, M.D. "The Relationship of Anatomy to the Fine Arts," by S. Messenger Bradley, F.R.C.S. "Our Water Supply." "Climate and Health in South Africa," by J. Bonwick, F.R.G.S. "The Waters of Kreuznach," by Drs. C. and F. Engelmann. "Some Substitutes for Alcohol," by Francis Vacher, F.R.C.S. Ed. "Some Teachings of Development," by E. A. Schäfer, F.R.S. "Improved House Ventilation," on Drs. Drysdale and Hayward's Plan. "On the Internal Use of Water for the Sick," by J. Forsyth Meigs, M.D. "Proceedings of the North-Western Association of Medical Officers of Health."

⁂

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, January 28th:—"Headaches: their Nature and Treatment," by W. H. Day, M.D. (third edition). "Student's Guide to Surgical Anatomy," by E. Bellamy, F.R.C.S. (second edition). "Student's Primer on the Urine," by J. Travis Whittaker, M.D. "Pseudo-Hypertrophic Muscular Paralysis," by W. R. Gowers, M.D. "The Spectroscope in Medicine," by C. A. MacMunn, M.D. "Klein and Smith's Atlas of Histology," part x. "The Half-yearly Retrospect of Medicine," edited by Drs. W. and J. Braithwaite, vol. lxxx. "Handbook of Therapeutics," by Sydney Ringer, M.D. (eighth edition). "Aids to Physiology," by B. Thompson Lowne, F.R.C.S. "Aids to Materia Medica and Therapeutics," by Armand Semple, M.D. Cantab. "Pharmacology and Therapeutics," by Lauder Brunton, M.D., F.R.S. "Minor Surgery and Bandaging," by Christopher Heath, F.R.C.S. (sixth edition). "Cancer of the Rectum," by W. Harrison Cripps, F.R.C.S. "Bentley and Trimen's Medicinal Plants," parts xxxviii.—xlii. "Movable Atlas of the Ear and Teeth," by Lennox-Browne, F.R.C.S.Ed., and Hy. Sewill, M.R.C.S. "Water Analysis," by E. Frankland, F.R.S. "Contributions to Cardiac Pathology," by J. Cockle, M.D. "Observations of Fatty Heart," by H. Kennedy, M.D.

◆

## THE APPOINTMENT OF REGISTRAR-GENERAL.

IN the House of Lords on Friday Feb. 13, the Marquis of Lothian asked the First Lord of the Treasury, with reference to the recent appointment to the office of Registrar-General, whether the long services of Dr. Farr had been taken into consideration, and whether he would state why Dr. Farr had not been selected as the successor of George Graham Esq., in that office. It seemed generally to be assumed that a public servant in the position of Dr. Farr, unless promoted when a vacancy occurred, such as the one to which reference was made in the question, was under the imputation of having something against him. An impression had arisen among the medical profession, which he was sure was altogether owing to a misapprehension, that Dr. Farr was not promoted simply because he was a member of the medical profession. He was quite sure that in appointing Sir Brydges Henniker, there was no intention whatever to throw any reflection upon that profession; and he was sure the noble Earl would agree with him that it would be unfortunate if such an impression were allowed to remain.

The Earl of Beaconsfield said that it was the original wish of the Government to appoint Dr. Farr to the post. He had obtained a very high reputation by his labours in his office; they had always been admitted, and they had been amply recognised by the public and the State. But when he (Lord Beaconsfield) had to make those inquiries which were necessary before the appointment was made, such a representation was made to him as to the state of health of Dr. Farr, that he shrank from the responsibility of appointing him to discharge the very arduous duties of the office of Registrar-General. He had before him an official document which had previously been sent in asking for a superannuation for Dr. Farr; and the statement of his health in that document, combined with his advanced age—seventy-two—was such that he felt confident that not one of their lordships would feel himself authorised, after reading the document, to appoint Dr. Farr to the office. That was the only ground on which the Government proceeded; and as to supposing that there was a prejudice on the part of the Government against the appointment of a medical man to an office the duties of which were intimately connected with the acquisition of statistics relating to life and death, he was sure their lordships would, without a moment's hesitation, acquit him, or any person who might occupy his present position, of being influenced by such considerations. After he found it impossible to appoint Dr. Farr, the office was open for a considerable period, and many names were sent in. He selected the gentleman who had received the appointment because, on the whole, he believed him most competent to fulfil its duties. He was an individual with whom Lord Beaconsfield had no personal acquaintance, but who in his mind gave the greatest promise of the ability to fulfil duties of the greatest importance, and which certainly required health and vigour for their performance, particularly when preparations were being made for taking a new census.

It is but right that the profession should have before them the full statement of the Premier as to the supersession of Dr. Farr. In connection with that statement it is as well to point out that it has been publicly asserted that the application from Dr. Farr for superannuation, which the Premier here quotes as his reason for not appointing that gentleman, was not in existence at the time when it was decided to give the office to the son-in-law of Lord John Manners. The application for a pension was laid before Government by Dr. Farr after he had been put aside in favour of the ex-Captain of Horse Guards, and was a natural expression of indignation by Dr. Farr at the slight put upon him, rather than an assertion of his incapacity to do the work. But, if the Premier had other reasons for thinking that Dr. Farr was incapable of discharging the duties effectually, we would venture to inquire why, if Dr. Farr were as incompetent for the office of Registrar-General as he is represented to have been, he was not removed from that office? He has all this time been Registrar-General in fact, though not in theory, Major Graham being nobody, and, notwithstanding his supposed incapacity, the Department has thriven, and continued to thrive. If the Prime Minister considered him incompetent, why did he not let him go out on a pension long ago? If he thought him an effective officer, why did he not continue him in office? But, if Dr. Farr be competent for the duties which he has discharged so long and so well, surely he is no more incompetent than Major Graham or Sir Brydges Henniker; and why should not educated incompetency, as represented on Lord Beaconsfield's showing, by Dr. Farr, be as good as uneducated incompetency in the person of Sir Brydges Henniker.

We cannot, of course, dispute the Prime Minister's assertion that that gentleman "was the one amongst many competitors who (to his mind) gave the greatest promise of performing efficiently the duties of the office." All we can say is that, so far as we know of public opinion amongst statisticians and the medical profession, the Prime Minister adds to his other distinctions that of being the only person in the United Kingdom who holds such an opinion. We do not know that any person or any newspaper has attempted to justify the appointment of Sir Brydges Henniker on the ground of his fitness, though many have tried to throw dirt on Dr. Farr. But perhaps Lord Beaconfield thinks that statistical competency can only belong to the relatives or *protégés* of Ministers.

## SUPERANNUATION OF DR. FARR.

WHILST at press, we learn that Her Majesty's Government have decided to award Dr. Farr a special retiring pension of £800 a year, which was the full salary of his office.

## THE RECENT ELECTION AT DR. STEEVENS' HOSPITAL, DUBLIN.

WE referred last week to the fact that Drs. Tweedy and Hayes had been chosen as physicians to Dr. Steevens' Hospital, Dr. Warren, the Lecturer in Anatomy in the School of the Hospital, being rejected, although supported by a strong representation by the managers of the School.

It would seem as if this requisition by the managers of the School was resented by the Board of Governors of the Hospital, who, in great majority are non-medical men, as an interference with their free choice, for, as our readers know, they did not elect Dr. Warren, but chose Drs. Tweedy and Hayes to occupy the two vacancies. We understand that the result of the election created great excitement in the School and Hospital, the professors who supported Dr. Warren feeling themselves naturally the subject of a great slight on the part of the Board of Governors, while the students, and even the patients, took sides in the dispute, and, we hear, were guilty of very outrageous conduct towards the newly-elected physicians.

In the interest of Dr. Steevens' Hospital, no less than of its School, we much regret these occurrences and deplore the unsatisfactory position in which both institutions are placed by the act of the Board of Governors. As to the School, we believe we may say that the decision of the Board will result in its extinction, for the anatomical teaching within nas been hitherto conducted, in great measure, by Dr. Warren, in conjunction with the late Dr. Bookey; and it is not likely thar Dr. Warren will continue the work of teaching when the reward of his work for which he might reasonably hope has been denied him. If this be so, the Hospital will lose most of its student-class, and will cease to be a clinical hospital or a teaching, institution.

As to the Hospital, the effect is no less serious. That Board has chosen Dr. Henry Tweedy, who certainly had a strong claim to their consideration, and, as far as we know, is entirely worthy of the office to which he has been appointed, but in their eagerness to "snub" the School the lay governors have, in our opinion, done a grievous injustice and seriously imperilled the interests of their hospital by putting into the physiciancy another gentleman in place of Dr. Warren.

The new physician possesses, indeed, the legal qualifications, but as he obtained his surgical qualification last year and his medical licence the year previously, we cannot be expected to credit him with such experience as might entitle him to the custody of the lives and health of an hospital full of patients. The right to such a position should be, and in all well-ordered public institutions is, acquired by industry and experience, and we can hardly suppose a gentleman who two years ago was a student, and since then has not proved his competency in any large public work, possesses such a large special wealth of these qualities as to place him above the head of a gentleman who has done good and true work in the institution for twelve years. We congratulate the profession on being no party to this job.

## DR. RICHARD RAINSFORD.

THE roll of those who have been lost to the profession within a recent period is increased this week by the death of Dr. Rainsford, surgeon to St. Mark's Ophthalmic Hospital, which took place on Tuesday week at his residence in Merrion Square, after a very long and painful illness.

Dr. Rainsford graduated in medicine and surgery at Trinity College, Dublin, in 1869, and shortly afterwards proceeded to Vienna to study ophthalmic and aural surgery under the eminent teachers at that University, where he soon so distinguished himself by his energy and talent, that Professor Politzc appointed him assistant at his well-known clinique in the Allgemeines Krankenhaus.

On his return to Dublin, in 1872, he became attached to St. Mark's Ophthalmic Hospital, first as curator of the Pathological Museum, and afterwards as assistant-surgeon, and at the same time he entered on the duties of demonstrator in the Ledwich School of Medicine, where his remarkable powers of exposition and unfailing kindliness of disposition soon rendered him one of its most popular teachers, and made his appointment as lecturer in ophthalmic and aural surgery, in 1875, a matter of universal satisfaction.

About this time, while making a pathological examination of a terribly diseased body, he received a poisoned wound, which was undoubtedly the origin of chronic abscesses, causing him untold suffering during the last two years of his life.

He obtained the Fellowship of the Royal College of Surgeons (by examination) in 1874, and was made ophthalmic and aural surgeon to the Adelaide Hospital in 1876. Shortly afterwards, on Sir William Wilde's death, he was promoted to the post of junior surgeon to St. Mark's Hospital, a post which he only held until Mr. Wilson's death in 1817, when he was elected unanimously senior surgeon to the hospital. This position he held for nearly three years, during which he was incessantly working for the interests of the institution, and it is mainly owing to his exertions that the late improvements and alterations have been so successfully carried out. This period of his life, however, was marred by frequent and severe attacks of that malady which eventually carried him off in the full bloom of professional success, and we know that it was in this severe school of personal suffering that he acquired that ready sympathy and unfailing kindness of manner and of heart which so endeared him to his large circle of patients and friends. His powers of endurance were very great, and when suffering from that which would have prostrated almost any one but himself, he would go about his work as usual, sacrificing himself utterly to his professional duties, and there can be little doubt that his disregard for his own health in this respect hastened his end.

**University of Dublin.**—The following degrees were conferred last week :—

*Bachelor in Surgery.*

Cohen, Abraham
Darling, John Singleton
Moore, Malcolm Henry
Silcock, Alexander
Smith, David Chadwick

*Bachelor in Medicine.*

Dixon, Charles Hampden
Hickson, Richard Charles Coleman
Kane, John Seymour
Lucas, Thomas John Rashleigh
Mason, Alfred
Moore, E. Erskine
Mouillot, Francis Albert
Patton, William Johnstone
Silcock, Alexander
Smith, David C.
Studdert, Richard Charles

*Doctor in Medicine.*

Dudley, Henry Nathaniel
Hickson, Richard Charles Coleman
Poole, Jonas Sealy

**Army Medical Department.**—List of candidates who were successful for appointments as Surgeons in Her Majesty's British Medical Service at the competitive examination held in London on 9th February, 1880 :—

| No. | Name. | Marks. |
|---|---|---|
| 1. | Sylvester, G. H. .. | .. 1925 |

# NOTICES TO CORRESPONDENTS.

### "A KNOT IN THE UMBILICAL CORD."

*To the Editor of the* MEDICAL PRESS AND CIRCULAR.

SIR,—In answer to "Inquirer," I beg to state that the week before last I met a case of perfect knot in the umbilical cord, being the second which I have recognised in the course of my practice. The cord was very long, and wound round the thigh of the infant, but did not in any way interfere with the successful treatment of the labour.

I am, Sir, yours, &c.

Portlaw, Feb. 20. JAMES MARTIN.

AN EX-STUDENT.—Again held over for more pressing matter.

HARVEIAN SOCIETY OF LONDON.—Thursday, March 4, at 8.30 p.m., Mr. George C. Coles, "Cases of Cyphosis."—Dr. Percy Boulton, "Typical Development of Children."

ROYAL MEDICAL BENEVOLENT COLLEGE.—Candidates for pensionerships or scholarships must deliver their applications to the Secretary at the offices in London on or before March 3rd. The election takes place in May.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—This day (Wednesday), at 5 p.m., Gulstonian Lectures: Dr. Gowers, "On Epilepsy."

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 8 o'clock, Dr. Stephen Mackenzie will show a Case of Urticaria Pigmentosa (living subject), and read a paper "On Annular Stricture of the Intestine."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Friday, Feb. 27, at 5 p.m., Gulstonian Lectures: Dr. Gowers, "On Epilepsy."

CLINICAL SOCIETY OF LONDON.—Friday, Feb. 27, at 8½ p.m., Mr. Teevan, "A Case of Retention of Urine from Impacted Urethral Calculus, relieved by pushing the Stone back into the Bladder and Crushing it."—Dr. Buzzard, "A Case of Paraplegia from Pott's Disease, treated by Sayre's Splint; Intestinal Obstruction; Death from a Kink in the Duodenum." "A Case of rapid and almost universal Paralysis, involving the four Extremities, both sides of the Face, Respiration and Deglutition; Recovery."—Dr. Sangster, "A Case of Molluscum Fibrosum."—Dr. Greenhow, "A Case of Typhoid Fever, with Acute Nephritis and Profuse Hæmaturia."

QUEKETT MICROSCOPICAL CLUB.—Friday, Feb. 27, at 8 p.m., Dr. T. Spencer Cobbold, "On Human and Canine Filariæ."—Dr. Sylvester Marsh, jun., "On Bleaching and Washing Microscopical Sections."

### THE LATE DR. O'LEARY, M.P.

*To the Editor of the* MEDICAL PRESS AND CIRCULAR.

SIR,—Feeling interested in the movement on foot to raise a substantial fund to aid the family of the late Dr. O'Leary, allow me the opportunity, through your columns, to suggest to the several Poor-law medical officers of Ireland to subscribe, say even a pound each, which, in the aggregate, would be a large amount. Dr. Lyons, one of the treasurers of the Fund, would, I am sure, take charge of it and hand the sum in as the united mite and aid from the Irish Poor-law medical officers. I have no doubt the Council of the Irish Medical Association would give a stimulus to it if, on the adoption of a resolution recommending to their several members the desirability of assisting in their present distress the family of him who felt always willing and anxious to support at any inconvenience every movement, in and out of Parliament, that might be calculated to better the position of the Irish doctor.

It is my intention to issue a circular to the coroners of Ireland asking them to subscribe to the Fund, and to remind them that the poor fellow for whose family we now plead always gave practical proof of supporting any measure in Parliament to serve the interests of the coroner.

I am, Sir, your obedient servant,
F. J. DAVYS, B.A., F.R.C.S.I.,
Coroner, co. Dublin.

## VACANCIES.

Buckingham General Infirmary, Aylesbury.—Resident Surgeon. Salary commencing at £80, with board. Applications to the Secretary on or before Feb. 28.

Carmarthen County Infirmary.—House Surgeon. Salary, £125. Applications to the Secretary, King Street, Carmarthen, before March 31.

Chatham.—Assistant House Surgeon for the St. Bartholomew's Hospital. Salary, £80, with board. Applications to the Clerk of the Trustees before April 14.

Manorhamilton Union, Drumkeeran Dispensary.—Medical Officer. Salary, £100, with fees. Election, March 5.

Metropolitan Asylum District, Leavesden Asylum.—Two Assistant Medical Officers. Salary of first Assistant, £150; of second, £120, rising to £150, both with board. (See Advt.)

Navan Union, Painestown Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election, Feb. 27.

Rathdown Union, Bray and Rathmichael Dispensary.—Medical Officer. Salary, £110, with fees, and £27 as Medical Officer of Health. Election, March 8.

St. Pancras Infirmary.—Honorary Physician. Applications to the Hon. Sec., 126 Euston Road, London, before March 2.

◆

## APPOINTMENTS.

BALLANCE, C. A., L.R.C.P., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital.

BROOM, C., M.R.C.S.E., Medical Officer for the Wednesfield District of the Wolverhampton Union.

CULLIMORE, D. H., M.K.Q.C.P.I., F.R.C.S.I., a Physician to the North-West London Hospital.

DE LA HUNT, J. J., L.R.C.P.Ed., L.R.C.S.Ed., Medical Attendant to the Royal Irish Constabulary, Lawrencetown, co. Galway.

EWART, W., M.B., M.R.C.P.L., Assistant Physician to the Hospital for Consumption, Brompton.

FISHER, F. C., M.R.C.S.E., Assistant House Surgeon to St. George's Hospital.

HATTON, G. S., M.R.C.S., Assistant House Physician to St. Thomas's Hospital.

LUNN, J. R., L.R.C.P., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

MADIGAN, B., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Kilrush Union Workhouse.

MCHARDY, M. M., F.R.C.S., Professor of Ophthalmology to King's College, and Ophthalmic Surgeon to King's College Hospital.

NEWSHOLME, A., M.R.C.S., L.S.A., House Physician to St. Thomas's Hospital.

PHILPOT, B. P., L.R.C.S.I., an Assistant House Surgeon to the Liverpool Dispensaries.

SHAW, J., M.R.C.S., L.S.A., House Physician to St. Thomas's Hospital.

SHEPPARD, C. E., M.B. (Lond.), M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.

SMITH, R. P., M.B. (Lond.), M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.

WADE, J. J., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer and Medical Officer of Health for the Lettermore Dispensary District of the Oughterard Union, co. Galway.

WILLIAMSON, R. J., M.A., M.B. (Oxon.), M.R.C.S., L.R.C.P., Assistant House Physician to St. Thomas's Hospital.

◆

## Births.

BROWNE.—Dec. 26, 1879, at Anson Street, Orange, N.S.W., the wife of Valentine E. Browne, M.B., T.C.D., of a daughter.

CREAN.—At Clonmel, co. Tipperary, the wife of Thos. Crean, L.R.C.S.I., of a son.

DOLAN.—Feb. 6, at Horton House, Halifax, Yorks, the wife of T. M. Dolan, F.R.C.S.Ed. of a son.

HIGGINSON.—Feb. 15, at Bridge House, Bangor, the wife of H. Talbot Higginson, M.D., L.R.C.S.I., of a son.

ROBINSON.—Feb. 16, at Newry, co. Down, the wife of William Robinson, L.K.Q.C.P., Newtownhamilton, of a son.

◆

## Deaths.

BROWN.—On Feb. 17, at Steeple Bumpstead, Essex, Alex. Brown, M.R.C.S., in the 86th year of his age.

DE MIERRE.—On Feb. 19, at Ben Venue, Torquay, Albert de Mierre, M.D., aged 75.

EWART.—On Feb. 17, suddenly, at 21 Rubislaw Terrace, Aberdeen, Jessie Caroline Schafer, wife of J. Cossar Ewart, M.D.

HALL.—On Feb. 4, at Malta, Surgeon-Major A. R. Hall, of dysentery contracted when serving in Afghanistan.

JONES.—On Feb. 14, Llewelyn Jones, M.D., for many years in active practice at Beaumaris, Anglesey, aged 78.

O'LEARY.—At 111 Jermyn Street, London, W. H. O'Leary, F.R.C.S.I., M.P., aged 41.

RAINSFORD.—On Feb. 17, at 2 Merrion Square West, Dublin, Richard Rainsford, M.B., T.C.D., F.R.C.S.I.

SOPWITH.—On Feb. 7, at 1 Calverley Parade, Tunbridge Wells, Henry L. Sopwith, F.R.C.S.E., aged 71.

TRIBE.—On Feb. 16, at Strood Hill, near Rochester, Benjamin Tribe, M.R.C.S., late of Chatham, aged 85.

## OF THE
## GULSTONIAN LECTURES ON EPILEPSY,

*Delivered before the Royal College of Physicians of London,*

By W. R. GOWERS, M.D., F.R.C.P.,

Assistant Professor of Clinical Medicine, University College; Physician to the National Hospital for the Paralysed and Epileptic.

### LECTURE II.

THE second lecture was devoted to a consideration of some of the symptoms of the series of cases of epilepsy which formed the subject of the lectures. The first point examined was the time at which attacks occurred. Of 840 cases, the attacks occurred by day only in 2-5ths, and at night only in 1-5th; by both day and night in about 2-5ths. No difference in this respect was observed between the cases of epilepsy and hystero-epilepsy. In epileptics the first fit occurred rather more frequently by day than by night: in hystero-epileptics it was much more frequent for the first fit to occur by day. Applying certain other facts to prognosis, it was shown that if the first attack is in the day the probability is as six to one that some subsequent fits will occur in the day: and only one in seven that all will occur in the night: the probabilities are equal that the future attacks will or will not be confined to the day, and that some attacks will or will not occur in the night. If the first attack is in the day, the probabilities are, each, two in five that subsequent fits will be confined to the night, or will occur both day and night, and the probability is five to one against the attacks being confined to the day. If fits which have been established by night begin by day they commonly cease by night. If fits which have occurred by day commence to occur at night, they commonly cease by day; but when fits which have occurred only at night, occur by day, they commonly cease at night. Of 82 cases in women no attacks occurred at the menstrual period in one-twelfth. There was no difference at those times in one-third. In half, the attacks were worse at those times, most commonly before, less commonly during, and least commonly after the period.

Of the symptoms of attacks, their modes of onset was selected as the most important for detailed analysis. It was pointed out that the aura is the subjective effect of the commencing change in the brain, of the character of which it gives information to be obtained in no other way. It differs in character according as the "discharge" begins in a structure subserving sensation, motion, or an intellectual process. Of 1,000 cases, an aura was present, at least occasionally, in 505. The various modes of onset were classified in seven groups, each of which was considered in detail:—(1) Unilateral peripheral auræ present in 86 cases. Of five cases, beginning in the tongue, all were right-sided, which suggests (as does its paralysis, often marked in aphasia) that the movements of the tongue are chiefly represented on the left side of the brain. In 16 cases the commencement was in the face, much more frequently by a motion than by a sensation. In 40 cases the commencement was in the arm; when by a spasm it was almost always in the hand as a whole, or in the arm as a whole; but when by a sensation (14 cases), the commencement was almost always in a definite part of the hand, and never higher up the arm than the wrist. Commencement by motion, or by motor sensations, was equally frequent on the two sides. Simple sensations were twice as common in the left hand as in the right. The aura passed, in some cases, up to the head or mouth, and in others down the side to the leg, while in others there was a second commencement in the foot. The onset was in the leg in 14 cases—5 by distinct motion, 5 by sensation In some cases the aura passed up the side to the head, and in some up the side and down the arm: in some cases up both limbs. There are thus two ways in which the limb secondarily affected may be involved. Reasons were given for believing that, in the cases in which the aura passes from one limb to the other by the trunk, the sensory centre leads in the discharge. No aura beginning in the tongue, face, arm, or leg, was associated with one in the special senses, but the latter occurred in three cases commencing in the arm by a sensation. The progress of some limb auræ as from the face to the arm and then to the leg, or from twitching outwards of the mouth to the rotation of the head, is explicable by the relations of the motor centres of the convolutions, but in other cases the progress of the aura cannot be thus explained, and reason was given for believing that in many of these latter cases the sensory centres, the position and relation of which are unknown, lead in the discharge.

The second group of auræ comprehend the bilateral sensations in the limbs and certain general sensations and motions. In eleven cases the commencement was in both arms, in twelve in both legs. Commencement in the trunk was rare, and almost always in the spine. All the cases with a spinal aura were epileptic, and most of them commencing in both arms, but many beginning in both legs were hystero-epileptic. General tremor, or startings, malaise, and faintness, marked the onset in fifty-one cases; almost all those beginning with the two former were purely epileptic, but many beginning with malaise or faintness were hystero-epileptic.

The third group are visceral auræ, referable chiefly to the region of the pneumogastric. An epigastric sensation was present in fifty-one cases, sometimes felt to the left of the epigastrium, never to the right. Whenever it was actual pain it remained at the epigastrium till consciousness was lost; when vague it often passed to the head and throat. The latter sensation seems referable to the respiratory function of the pneumogastric, that remaining at the stomach to its gastric function, and the latter was often associated with nausea, sometimes with actual retching. Cardiac sensations constituted the aura in sixteen cases. Hystero-epileptic cases constituted about a third of this group.

In the next group were placed the cases beginning with a sensation of vertigo or actual rotation; these were ninety in number, almost all epileptic. The fifth group comprehended the sensations referred to the head, present in fifty, pain in twenty-one, vague sensation in twenty-nine. In one-fourth of each the attack was hystero-epileptic. The sixth group was constituted by the psychical auræ, present in twenty-five cases, an emotion in ten, an idea in fifteen. The emotion was always fear, and the attacks always epileptic. The idea which preceded the other attacks could not always be described, but in some it was elaborate, and sometimes consisted in a sudden recollection of many past events.

The last group constituted the auræ referred to the special senses and their organs, present in 119 cases. Sensation of smell, usually unpleasant, preceded the fits in seven cases. In only one was there a gustatory aura. A sensation in the eyeball was present in seven cases; double vision preceded the attacks in five; apparent increase or diminution in the size of objects were occasional auræ; loss of sight (inhibition of the visual centre) was the aura in twenty-six cases, and in no less than forty-six the aura was a visual sensation (discharge in the visual centre); in nine cases it was merely light, in seventeen colour. Red and blue were the most frequent, never both absent, and no other colour was ever seen alone.

The order of frequency of colour, was red, blue, green, yellow, and purple once. This order does not correspond to the lengths of light unto the visual fields, but it is not far from the order of visibility of colours as determined by Cohn, which is red, blue, and green equal; yellow, violet. In fourteen cases the aura was a highly specialised visual sensation, a visual idea. In one case very complex auditory, visual, and olfactory sensations separated the two parts of an epigastric throat aura. The only known autopsy on a case of organic disease with a visual aura was one recorded by the lecturer, in which a tumour was found on the occipital lobe extending up to the centre for vision in the angular gyrus. Auditory auræ were present in twenty-five cases; in six auditory loss, a sudden sense of stillness; in twenty-one auditory sensations, in some low in specialisation, in others auditory ideas, and some of the latter were associated with visual ideas of corresponding elaboration. A case (Dr. Hughlings Jackson's was mentioned in which fits with an auditory aura were due to a tumour within the upper temporo-sphenoidal convolution, in which the auditory centre is located by Ferrier.

One or two other points on the symptoms of epileptic attacks were then alluded to. Pallor of face, present at the commencement of some attacks, is, it was urged, often absent from the first in both major and minor seizures. The tonic and clonic spasm is continuous: the interruption in the former can be felt by the hand before it is visible to the eye. The hands are not always clenched, but are often in the position resulting from the action of the interossei, the wrist also being strongly flexed: an exaggeration of the posture in tetany.

The cases presenting co-ordinated spasms were then described. Hystero-epileptic attacks, often called hysterical, but presenting alliances with epilepsy and mania, as well as with hysteria. Four varieties seen in this country were sketched. The first presents sometimes after tonic spasm, wild movements, opisthotonos, paroxysms of terror, and a tendency to bite, often in a curiously animal manner. The second is characterised by emprosthotonic spasm; the third, by rhythmical movements of flexion and extension of the legs; the fourth, by intense dyspnœa. These forms are common in girls, women, and boys, but the first occurs also, in most severe type, in men. In women ovarian pressure may rarely arrest, but does not produce the attacks, and they could always be cut short more readily by other methods.

## DOMESTIC SCAVENGING. (a)

By CHARLES F. MOORE, M.D., F.R.C.S.
Late Physician to the Cork Street Fever Hospital, Dublin; Examiner in Materia Medica, Queen's University; One of the Medical Officers of Health, Dublin City, &c.

THAT part of the important subject to which I would ask the attention of the Society of Metropolitan Medical Officers of Health, on the present occasion, is generally known as the ashpit system in Dublin; it is, however, in almost all cases rather that which is known in Great Britain as the midden-privy system, being in the greater number of cases in conjunction with the privy, especially in the case of tenement houses.

I have long been conversant with the ill results of the state in which these receptacles usually are in this city, and the matter has been urged upon me also by highly influential citizens, as an evil needing prompt and permanent remedy.

In certain instances, by repeated reporting, remonstrance, &c., amelioration has followed, but in many of the leading fashionable and important business localities, cases of great neglect, in this particular, exist at the present moment. It is hardly necessary to add that, in the poorer parts of our city, houses provided with sanitary accommodation have, in the great majority of instances, only this objectionable system to depend on.

It may be well to state that in most cases the ashpit is excavated to some depth below the surface; one was reported to me lately as a couple of yards deep—very rarely is it provided with either masonry or water-tight cement lining. Some are covered over, several are not, and the size is so considerable generally, that a very large accumulation occurs before the necessity of cleansing becomes apparent to the casual observer. In this way the air, as well as the soil and the surface-waters, become more or less saturated with offensive matter frequently perceptible, but in not a few cases only, by a certain heavy sickly odour rather than a downright stench.

It is not uncommon to find the tenants in localities where such nuisances exist, which, unfortunately, is rather the rule than the exception, complain that they are obliged to keep their windows closed to keep out the offensive effluvium.

---

(a) Read before the Society of Metropolitan Medical Officers of Health, Feb. 18, 1880.

In the great majority of cases these foul receptacles are built against the wall of a dwelling house; some have, and many have not, outlets in connection with the street sewers; a few are actually within the walls of the houses.

When the attention of the public and of the authorities was forcibly drawn to the state of the Dublin tenement houses by the occurrence of epidemics, the basements were, some time ago, in very many cases, being used as receptacles for filth of the most injurious description. In not a few houses, even in some of the best localities, the area cellars are even now used in this way.

When such places in close connection, in fact, forming with the scullery a part of the dwelling house, are used for ashes, bones, decaying animal and vegetable refuse, invariably also find their way into them.

Improvement has been effected in some cases, but a vast amount of nuisance still remains, and so long as it is so, and as other depositories of "matter out of place"—to use the late Lord Palmerston's definition of dirt—are allowed to continue, we need not be surprised to find the Dublin death-rate high, and the humbler classes resorting to the public houses rather than their own insanitary and therefore cheerless dwellings.

A resident in a court near St. Patrick's Cathedral wrote to me some time ago, complaining that the only overflow from a privy was over the court. Since the attention of the authorities was drawn to the case, I have not had any further complaints ot this court, and I notice it here, as it reminds me of what is by no means uncommon in some of the poorer parts of Dublin; instances of which I have seen to-day, namely, the backyard on a higher level than the ground of the floor of the house, and the yard being badly paved, and not having a proper fall to the sewer, if one exists, the surface drainage runs into the house—a highly objectionable matter, as this generally contains the overflow from the ashpit, &c.

If the house has a sewer it is generally very ill-constructed, and covered with flags, perforated with rat holes, and allowing the foul gases to escape into the houses. Several houses in New Row South, on the north side, are so situated. I have by me notes of a case of cellulitis of the neck in one person, and of fever in another, in a room on the ground floor of a house in that locality, the sufferers complaining of the effluvium of the sewer which passed from the backyard under the flooring.

I should but weary the Society were I to enumerate particular instances of defective ashpits. With your permission, Mr. Chairman, I will shortly state the usual defects I have observed in ashpits in Dublin; they are mostly far too large and badly constructed, are generally placed against, or too near, or in a position likely to injure the air entering dwelling-houses, or the soil cellars or basement storey of houses; they are constantly allowed to be overfull, and as at present existing are highly injurious from being in connection with the necessary. They are generally made the depository of liquid refuse from houses.

I will now conclude this part of my subject with the observations of two highly competent observers.

Dr. Martin Tuomy, writing on the causes of fever in Dublin in 1810, amongst others, enumerates foul, stagnant, corrupted air, as of dirty cellars and garrets, &c. He points out that these agencies are all the more potent and dangerous in seasons of distress, when food is scarce and bad.

The then medical officer of the Privy Council and Local Government Board, England, in his Report for 1874, wrote that, "of all the filth influences which prevail against human life in this country, privies of the accumulative sort operate undoubtedly to far the largest extent."

The largest factor at present in producing foul air is the ashpit receptacle, as above described, and the observation of Mr. Simon quoted above, is fully borne out by the system pursued in Dublin, aided in its deleterious influences by the large depôts permitted to exist in our city.

The Public Health (Ireland) Act of 1878 provides that no house shall be erected or re-built without sufficient water-closets, earth-closets, or privy accommodation, and an ashpit furnished with proper doors and coverings; thereby, as it seems, rather encouraging the continuance of a system fraught with danger to the public health, in the judgment of such eminent authorities as I have quoted above.

However, the sanitary authority has a check over these matters in the powers given them as evidenced in the words "sufficient," "proper," and in the Act generally, as well as in having the function allotted to them of making bye-laws with respect to buildings, streets, sites, &c., and for purposes of health.

The model bye-laws of the English Local Government Board order that every person who shall construct such an ashpit in connection with a building, shall construct such ashpit at a distance of *six feet* at the least from a dwelling-house or public building, or any building in which any person may be, or may be intended to be, employed in any manufacture, trade, or business.

A person who shall construct an ashpit in connection with a building, shall not construct such ashpit within the distance of ——— feet from any water supplied for use, or used, or likely to be used by man for drinking or domestic purposes, or for manufacturing drinks for the use of man, or otherwise in such a position as to endanger the pollution of any such water.

Every person who shall construct an ashpit in connection with a building, shall construct such ashpit in such a manner, and in such a position, as to afford ready means of access to such ashpit, and of removing the contents thereof, and, so far as may be practicable, in such manner, and in such a position, as to admit of the contents of such ashpit being removed therefrom, and from the premises to which such ashpit may belong, without being carried through any dwelling-house or public building, or any building in which any person may be, or may be intended to be employed in any manufacture, trade, or business.

Every person who shall construct an ashpit in connection with a building, shall construct such ashpit of a capacity not exceeding in any case *six cubic feet*, or of such less capacity as may be sufficient to contain all dust, rubbish, and dry refuse, which may accumulate during a period not exceeding *one week*, upon the premises to which such ashpit may belong.

It is unnecessary here to detail *in extenso* the other conditions obligatory in the construction of ashpits, except that it is provided that its floor, which must be flagged or asphalted, must be at least three inches above the surface of the ground adjoining; its walls must be of flagging or slate, or good brickwork nine inches thick, and rendered inside with good cement or asphalte.

Moreover, no ashpit is to communicate with any drain; a matter which urgently requires being carried out in Dublin, as indeed do all the details above specified, before we need hope for improved health for our citizens.

It is also ordered in England that no filth or wet refuse shall be thrown into any ashpit constructed and adapted for use only as a receptacle for ashes, dust, and dry refuse.

Very stringent directions are given for the construction of cesspools, which many of our ashpits in Dublin much resemble in use, but not in construction. Ashpits should be used as receptacles for dry ashes only. The construction of midden-privies as at present in common use in Dublin, should be entirely abandoned. In this paper I will not enter on the subject of what should be adopted in their stead.

In the removal of the contents of ashpits, as of all other refuse, the very stringent rules as to the use of properly-covered vessels, and the prevention of scattering filth and dust, and the clearing up of any that may unavoidably fall, should be adopted in Dublin. The wretched carts which are now used for the purpose here should not be tolerated.

I would especially press on my hearers the necessity of carrying out the *dictum* of the late medical officer of the Privy Council, Mr. Simon, namely, that the sanitary authority should aim at becoming "the preventer rather than the remover of nuisances; and so universally is this the fact that, bearing it in mind, sanitary authorities, when proceeding to think systematically of their duties, will generally find it advantageous to regard the prevention rather than the removal of nuisances as their main administrative problem."

The heavy death-rate of parts of Dublin where attention to the matters touched upon in this paper is much needed, must be my excuse for trespassing on your notice with a subject which, however necessary, cannot be agreeable to the health officer or the public generally, but that it demands constant thought and attention is seen when we find that the annual death-rate in many of the parts of our city, to which I have referred, varies from 35 to 100 per 1,000 annually.

# Clinical Records.

## LEEDS GENERAL INFIRMARY.

### *Case of Urticaria from taking Rosin.*

Reported by Dr. ERNEST H. JACOB,
Late Resident Physician.

E. T., æt. 36, was admitted into the Leeds Infirmary on Jan. 16, under the care of Dr. Clifford Allbutt. Ten days previously she had assisted in "laying-out" the body of a person who had been dead some days. She became sickly and ill after this, and the same day her bowels began to be loose. For this she took some powdered rosin—"about as much as two walnuts." The next day her face began to swell, and has continued so ever since.

On admission there is considerable swelling of the face, and she can hardly see. There is a slight papular eruption of urticarious character on her chest and arms. Urine, sp. gr. 1020, contains no albumen and gives no reaction or tarry odour on the addition of sulphuric acid.

She was ordered a mixture containing citrate of potassium, and a lotion of benzoic and hydrocyanic acid. She quickly improved, though at times there was severe itching, and was discharged in ten days' time.

This is a somewhat rare form of poisoning, and differed considerably in the appearance of the eruption from that produced by tar; nor was there the usual reaction of the urine with sulphuric acid obtained in that condition.

## CASE OF SECONDARY PUERPERAL HÆMORRHAGE.

By EBEN. DONALDSON, L.R.C.S.I.,
Medical Officer of Burt Dispensary District.

SUSAN D., æt. 40, a multipara, early in the morning of the 26th of last July, sent for me in great haste. As soon as I arrived I found her in a very weak state; blood was flowing in a small stream from the vagina. She stated that she had been confined twelve days before, and that when she got out of bed to pass her water early in the morning blood commenced to flow from her. She had had a quite natural labour. A neighbouring woman (not a midwife) attended her. I ascertained that a pillow-case had been used for a binder, and that it was not attended to after its first application. Patient did not leave her bed till the eleventh day after labour. She suffered from a constant cough, and during coughing the flow of blood was increased and clots were expelled. On making a vaginal examination I found the vagina hot, the uterus enlarged, and the os closed round something which felt soft, and which I concluded to be a clot of blood. Fundus was found to be as high as the umbilicus, and felt quite soft, and was not tender. I immediately proceeded to make pressure on the fundus, and to inject ergotin. Three minims of ergotin were injected into the glutæus muscle soon after my arrival, and three minims in about one hour and a half afterwards. The uterus to my great satisfaction very soon began to feel harder under my hand, and gradually became smaller, so that in the course of twenty minutes it could with difficulty be felt above the pubes. Hæmorrhage then entirely stopped. Patient, after the uterus contracted and the hæmorrhage ceased, complained of failure of sight and noises in her ears. She then fainted, and became pulseless and extremely pallid. She rallied soon after the exhibition of stimulants. Before leaving I applied a binder, and prescribed a mixture containing ergot. During the hæmorrhage no pieces of placenta or membrane were expelled as far as could be ascertained. With the exception of severe headache and other symptoms of "hæmorrhagic fever," which after some time passed off, recovery was uninterrupted. No abscess formed after the injection of the ergotin.

It appears that in cases of secondary puerperal hæmorrhage, with our present knowledge, it is impossible to say with any degree of scientific accuracy under what circumstances the enlarged uterus will contract when the stimulus of manual compression is employed. Barnes, in his excellent work on "Obstetric Operations," says:—"At an early period, that is, within two or three days after labour, you may squeeze out placenta or clot, by grasping the uterus firmly above the symphysis." He also observes, when speaking of the retention of clots mixed with fluid blood, "It is advisable, first, to try to empty the uterus by squeezing. If this is not satisfactory, the fingers or hand must be passed into the cavity."

This case is interesting, chiefly because it shows that we may hope to succeed in staying uterine hæmorrhage *twelve* days after delivery, by adopting the "expression" method without having recourse to the difficult alternative of introducing the fingers or hand into the uterus.

## HISTOLOGICAL EXAMINATION OF A CYSTIC KIDNEY.

By DR. CORNIL, of Paris. Translated from *Le Progrès Médical* by D. CAMPBELL BLACK, M.D., Physician to the Glasgow Public Dispensary, and formerly Extra-Physician to the Royal Infirmary.

THE large cysts contained either a liquid altogether transparent and colourless, or of citrine or rose colour. The colouration of the liquid was due to the presence of red blood corpuscles held in suspension.

The liquid of these large cysts, completely closed on all sides, was examined with a view to determining the existence therein of urea. It was found to contain urea in a sufficiently marked quantity. Two grammes of the liquid on analysis were found to contain 0·017 of nitrate of urea, and 0·0083 of urea, a quantity representing 4 gr. of urea per litre. It was of consequence to prove the existence of urea, for a distinction had been attempted between serous cysts (Rayer), in contradistinction to urinary cysts. The liquid contained albumen besides.

I have examined, in the fresh state, in water, the cellules lining the large cysts. They form a thin lining composed of one layer of flattened cells, having a large oval flat nucleus. Many of these cysts contained a thicker and more opaque liquid, even muddy sometimes, of a yellow-brownish or chocolate colour. In all these cysts there was then a greater quantity of red blood corpuscles, of round granular cells, epithelial cells, of granulo-fatty pus globules, and a large quantity of cholesterine crystals. In order to examine the kidneys on section I hardened fragments of the kidney by means of Muller's liquid, certain parts comprising the walls of the large cysts, other portions of the renal parenchyma which had almost retained its microscopical characters; there were, indeed, in the midst of innumerable cysts with which the kidney abounded, greyish portions where the renal tissue was easily recognisable by the naked eye. Even in those parts microscopic examination revealed cysts likewise.

*Walls of the Large Cysts.*—On fine section, including the walls of the large cysts, it is observed that they are composed of many layers of lamellated interstitial or connective tissue. That layer of connective tissue is more or less thickened, but generally it is thin and permeated by capillary blood-vessels, gorged with blood, and existing immediately under the epithelium, but not appearing on the internal surface of the cyst. Just without that fibrous layer are seen sections of the uriniferous tubes, which are small, atrophied, flattened parallel with the internal surface of the cyst, and lined with a peculiar layer of flat cells similar to those which exist in the loops of Henle. The epithelial lining of the large cyst is composed of a simple layer of flat cells, forming a thin membrane, easily detached, and which is here and there separated. These large cysts, which nowhere communicate with the uriniferous tubes, and which have not appeared to me at least to possess, either on their surface the vestige of vessels associated with the Malpighian capsule, teach as little regarding the origin of these pathological formations.

*Cysts of Medium Size.*—The smaller cysts, but still visible to the naked eye, which exist in portions of the solid renal parenchyma, examined on fine hardened section presented a variable aspect. Certain of them were almost of a round form, but frequently presented in their interior a projecting spur, which incompletely divided them in two portions; others were altogether spherical, but their cavity was frequently partitioned, one or more very fine partitions of the connective tissue following the diameter of the section indicated that the opening of a cyst proceeded originally from several distinct cavities, which ultimately opened the one into the other. Furthermore, at the periphery of these cysts there existed numerous *diverticula*. The partitions and *diverticula* of spheroidal form were always lined with a membrane of flattened cells.

In the interior of these cysts there were found sometimes only rounded lymphatic cells and red blood corpuscles, sometimes granular cells, at other times clear spherical bodies, without nucleus or granulations, with extremely fine and scarcely visible outline. These bodies of mucus or proteic matter were specially visible after their colouration by carmine, or better after the action of osmic acid. The osmic acid, indeed, enabled it to be seen that they were composed of a small mass of transparent substance, slightly coloured but solid. These little bodies, from fifteen to twenty-thousandths of a millimetre in diameter, sometimes filled the entire cystic cavity. We have been able to observe them emanating from the interior of the cells which line the wall of the small cysts, for there were here frequently numerous epithelial cellules, presenting in this protoplasm a cavity, either empty or occupied by one of these masses of mucus. The cysts of medium size justify the belief, owing to the presence of the walls which divide them, and of processes and *diverticula* at their periphery, that they proceeded from an irregular sinous dilatation of pre-existing uriniferous tubes. Their general form, their divisions and peripheric *diverticula* absolutely excluded the hypothesis that they sprung from dilatation of the Malpighian capsule, for in that case we should have had to do with cysts regularly spherical and not partitioned.

*Dilatation of the Uriniferous Tubes.*—An examination of the more compact portions of renal tissue confirmed the foregoing opinion by demonstrating the communication of small microscopic cysts with the uriniferous tubes, or rather with irregular dilatations of the tubes. On section of these parts there were observed indeed complete dilatations of a tube four or five times the diameter of the tube with which it was in direct communication, or rather these were the successive sinuous dilatations of the same tube separated by processes. These dilated tubes constituted cavernous islets in contact with one another, separated only by their partitions of renal connective tissue. It is easy to comprehend in regarding these islets of dilated tubes separated by their partitions, that a little more dilatation or a little more thinning of the walls would suffice to transform an islet of these tubes into a cyst of medium size, the cavity of which will remain yet a certain time partitioned, and whose borders will show *diverticulà*. It is thus easy, after having constituted the descending scale of cysts from the more voluminous to the smaller, to ascend from the latter to the greater, and perfectly to comprehend the mechanism of their formation. The islets of dilated tubes are surrounded by renal tissue of which the connective tissue is thickened, and the tubes and glomeruli atrophied Here, indeed, a zone exists in which the thickened connective tissue is infiltrated by small round cells, transformed into embryonic tissue. The tubes are small, compressed by fibrous tissue, and internally contain colloid cylinders. The capsuli of the glomerulus is thickened and undergoes fibroid atrophy, and around the islets of dilated tubes in course of becoming cysts, all the lesions, in a word, of interstitial nephritis, are found. Hence we are constrained, after this histological examination, to agree with the views of Virchow regarding the production of renal cysts. It is rare to find, post-mortem, complete cystic transformation of the two kidneys, while large cysts of one kidney are not infrequent. Rayer has figured two cases; one of the two is comparable to our case (pl. xxxvi., figs. 1 and 2). Cruveilhier gives likewise a good example (6th book, pl. iv., figs. 1 and 2). Lebert, one case (pl. cxxxviii., fig. 4). The *Bulletins de la Société Anatomique* also contain some good examples reported by Tavignot (1840), by Vigla (1837), and by Jessé (xxixth year), &c.

In all these cases the patients died with cerebral symptoms without cerebral lesions (uræmia), except in Jessé's case, where the patient succumbed to an attack of pneumonia. Almost always the urine contained albumen. The clinical history of our patient, apart from the lesions found after death, demonstrates that extensive changes of the two kidneys may exist without any appreciable concomitant phenomena. There can be no doubt that in our case the urinary excretion must have been long imperfect. In short, to the portion of renal substance forming cysts, and thus incapable of secretory function, must be added the periphery of these cysts where the uriniferous tubes are either compressed between adjacent pouches, or strangled by connective tissue of new formation, rendering the excretory surface very circumscribed. The slowness, however, of the morbid process permits a kind of adaptation on the part of the system, to the new order of things, and alone explains the compatibility of life with such lesions. A supplementary excretion takes place by the skin and the intestines. But in such cases a trifling cause frequently suffices to destroy the new equilibrium thus established, and suddenly to determine irremediable consequences.

## THE RELATIONS OF MEDICAL MEN TO THE CORONER'S COURT.

The following report of the proposals and subjects discussed at the recent meetings of medical men to consider their relations with the Coroner's Court, has been drawn up by Dr. Thomas, the Deputy Coroner for Central Middlesex, and Dr. Steavenson, and has been submitted to Dr. Hardwicke, the chairman of the meetings, and received his sanction.

The first question discussed was the desirability of the coroner appointing skilled pathologists to make the post-mortem examinations. It was suggested by medical men present that the examinations would often be more skilfully performed, and the evidence given before the coroner and his jury of a clearer and more definite character. It would also lessen the probability of medical witnesses engaged in general practice getting dissection wounds, or carrying septic poison to their puerperal patients. On the other hand it was contended by some that for the most part the post-mortem examinations were sufficiently well made by the general practitioner, and that only in certain cases were the services of an expert required.

The first resolution proposed and carried was :—

> "That the coroner be requested to accept the services and receive the evidence of a skilful medical gentleman in such cases where the medical man called in at death does not desire to make the post-mortem examination, the fee for which (one guinea) should be paid by the medical man desiring such services."

In the course of the discussion reference was made to the injustice under which the medical officers of hospitals and other medical institutions suffer by being obliged to give evidence in the Coroner's Court without remuneration, should the deceased person die within the walls of the said hospitals or infirmaries.

Many of the difficulties at present surrounding the procedure of the Coroner's Court were brought prominently forward. For instance: The difficulty a medical man is placed in when he feels conscientously obliged to refuse a certificate, either from want of knowledge of the real cause of death without a post-mortem examination, or from a feeling that his services have been called in too late for him to do any good, and obviously only for the purpose of obtaining a certificate.

Also the question: Whether the medical man should be responsible for putting the Coroner's Court in motion; or whether it should be made compulsory on the friends of the deceased person to communicate with the coroner when a medical certificate is not procurable.

Those present strongly objected to any discretion in the matter being left to the Registrars of Deaths. The weight of opinion seemed to favour the proposal that in cases in which a medical man had been called in, and was unable to give a certificate either from insufficient length of attendance or any other cause, he should have a form supplied to him which he could fill up and send to the coroner stating his reasons for refusing a certificate, for desiring a post-mortem examination, or for suggesting an inquest.

In the case of persons dying suddenly without any medical attendance, it was left undecided whose duty it would be to acquaint the coroner that a death had taken place.

It was pointed out that a registrar is bound to register a death reported to him by the nearest relative or other person present at the time of death, without asking any questions besides those necessary for registration. Under the present law a man might murder his wife and claim that her death should be registered by the district registrar as caused by any complaint he might like to name, and the death, without a medical man's certificate, would simply be returned as "uncertified." An order for burial would possibly not be granted if the registrar had any reason to think that the death occurred under suspicious circumstances, but he could if he liked grant an order for burial without communicating with the coroner.

The second resolution proposed and carried was :—

> "That it is desirable to refer the friends of a deceased person to the Registrar in cases where the medical man called in cannot satisfactorily certify as to the cause of a death, but that the said medical man communicate the ascertained facts direct to the Coroner's office on a form to be supplied for that purpose, so that the coroner can form his judgment as to the necessity of holding an inquiry. The communication being of a private character."

In the course of the discussion it was pointed out—that a medical man need not use the printed form supplied by the Registrar-General when certifying as to the cause of a death, but may word a certificate as he likes; and if he states the cause of death the death would be registered as "certified." The printed forms are merely to lighten the labours of medical men, and to try and obtain a uniform system of registration.

And also—that it is not lawful to make a post-mortem examination of the body of a person found dead, or who had died suddenly without medical attendance, after the coroner or his officer has been communicated with, as is sometimes done at some of the metropolitan hospitals; the body becomes the property of the Crown, and cannot be examined or buried without an order from the coroner.

The third resolution proposed and carried was :—

> "That no registrar of deaths shall be entitled to give an order for the burial of a body without first receiving from a duly registered medical practitioner a certificate of the death as 'from natural causes; or a certificate from the coroner of the district after an inquest."

This would involve alterations in the Registration Act.

If the last three words of the third resolution were retained the number of alleged unnecessary inquests which are now held would be greatly increased.

Reference was made to the action of the Middlesex magistrates in the question of fees payable for inquests, and the charge brought against coroners of holding unnecessary inquiries. There is no doubt that many inquiries are held as to the cause of death which a post-mortem examination proves to be clearly natural; and to eliminate this large class of cases, it was proposed that the coroner should have the power of ordering a medical man to make a post-mortem examination, and to forward to him a written report of the result; and should the death be from natural causes the medical man should receive a guinea fee for his report, and no inquest be held. This would materially reduce the fees payable for inquests, and might prove more satisfactory to the medical profession and to the magistrates. But it was objected that the House of Commons and the public would not tolerate such an arrangement. By it each medical man would, upon occasion, take upon himself the office and duties of a coroner, and the proceedings would be of a private character. But if this objection holds good, and a public inquiry is considered necessary in all cases of uncertified death for the purposes of public safety and the repression of crime, then the county rates for coroners' inquests must be very much increased instead of diminished in the face of the objections of the Middlesex magistrates. The public cannot have this guarantee of personal safety, and at the same time grumble at the price they have to pay for it.

The objections to private inquiries above alluded to could be met in the following way: In cases of sudden death, unattended by suspicious circumstances, the coroner might allow a post-mortem examination to be made with the consent of the friends of the deceased, by a medical man appointed by him, and a report rendered for which the coroner should pay a fee, and if the report proved death from natural causes unaccompanied by any cruelty or neglect, a public inquiry should be dispensed with. No *compulsory* post-mortem examination should be made without a subsequent public inquiry.

If this proposal were incorporated in the new Coroner's Bill, the number of unnecessary inquests now held would be greatly reduced, and also the county rates.

[The resolutions, as passed at the meetings, have been given, although in some respects they seem to be contradictory to the opinions expressed in the report of the discussions, and do not appear to embody all the proposals which the members of the meetings meant them to include. The order in which the several subjects were introduced has, as far as possible, been retained.]

◆

## ROYAL MEDICAL BENEVOLENT COLLEGE: THE MODE OF ELECTION.

The following report has been drawn up by the Committee of Governors of the Royal Medical Benevolent College, for improving the mode of election of beneficiaries.

It will be remembered that, at the last general meeting of the Royal Medical Benevolent College, resolutions were carried, in accordance with the wish of a large majority of the governors and subscribers, suggesting a plan whereby the evils of canvassing inherent to the voting system might be much diminished, if not entirely remedied. The committee formed to promote this desirable object, wish to make it known as widely as possible that the College Council, fully accepting the verdict of the meeting, have proceeded to carry it out in its best sense; and the ensuing election will be conducted on the altered system.

A knowledge of the proposed alteration in the mode of election has already had its effect in sensibly diminishing the applications for votes which formerly took place, and it is confidently believed that canvassing, with all its attendant evils, will, under the new regulations, almost entirely cease.

The chief reason which led some warm friends of the College to disapprove of the then proposed alteration, was a fear that it would undermine the interest of many in the elections, and diminish the number of subscribers.

Our excellent College, however, like other charities, is, we fear, feeling the effects of the present hard times. The moment, therefore, appears very opportune for those who can afford to do so, to rally round the Institution, and to evince, in a practical way, their belief that the Royal Medical Benevolent College is now more than ever worthy of support.

It is extremely gratifying to hear that additional contributions have been already made to the College funds, on the broad ground that the evils of the old system have been practically done away with, and that the poorer members of the profession, their widows and children, will henceforth be relieved without incurring an unnecessary expenditure of time, money, and harassing labour, heretofore the only means of securing success at the elections.

On behalf of the Election Reform Committee—

CHARLES J. HARE, M.D., Chairman of Committee.
JABEZ HOGG, Honorary Secretary of Committee.

February, 1880.

The Committee appointed by the Council of the Royal Medical Benevolent College recommended the following resolutions, which have been adopted, and will be acted upon at the next election in May.

"That the resolution of the annual general meeting be adopted as a resolution of the Council, omitting the proposal to alter the bye-laws, and substituting the word 'March' for the word 'April' in the first paragraph.

"That the Committee of Examination consist of seven members of the Council, inclusive of the Treasurer, who is *ex officio* a member of all Committees, and that four be a quorum.

"That, at the Council meeting in March 1880, the six ordinary members of the Committee of Examination be elected by ballot, each member of the Council present at the meeting voting for not more than six members.

"That, at the Council meeting in March 1881, the three ordinary members of the Committee of Examination who are to remain members of the Committee during the second year be determined by ballot in the Council, and that, at the same meeting, three new members of the Committee be elected by ballot.

"That, after the year 1881, it be the rule that the three ordinary members of the Committee who have served for two years shall retire, and shall be for one year ineligible for re-election, and that, at the Council meeting in each March, three new members of the Committee shall be elected by ballot."

◆

## FRANCE.

(FROM OUR OWN CORRESPONDENT.)

PARIS, FEB. 12, 1880.

AT the Academy of Medicine last week, M. Vidal, of the St. Louis Hospital, read a paper on the "Treatment of Prolapsus of the Rectum by the Hypodermic injection of Ergotine." By this new procedure the author succeeded in curing three cases of prolapsus of the anus in adults. The solution that he used was composed of one gramme of the extract of ergot dissolved in five grammes of cherry laurel water; the amount injected at one time was fifteen to twenty drops. None of the injections were followed by inflammation or abscess. In one case where the prolapsus was of long standing, M. Vidal operated twenty-two times, leaving an interval of two days between each injection. After the twelfth injection the prolapsus was completely reduced.

The inconvenience, if not absolute danger attending the plug *à demeure* in certain uterine affections, has often been dwelt upon by many surgeons of note, but according to M. Després, these inconveniences have been singularly exaggerated, at least, when the plug is judiciously used. Against the most frequent affections of the uterus, M. Després has recourse to a very simple means of cure. The agent he employs is a medicated plug called *tampon de Lourcine*. The employment of this tampon can be traced back to the foundation of this hospital, but like many other excellent remedies, was abandoned. The principle to which it owes its virtue is sulphate of alum. This substance is buried in a piece of cotton wadding about the size of a walnut, and covered by a bit of fine linen. The plug thus formed is armed with a string to draw it out when desired. The quantity of alum used is two grammes. Vaginitis of the gravest type is cured in five or six weeks by the application of this plug. In ulceration of the womb caustics should never be used, which, according to Dr. Després, only tend to aggravate the wound. The plug, on the contrary, succeeds admirably, presenting a double mode of action. It is endowed with astringent properties resulting from the dissolving of the alum in the utero-vaginal liquids. It acts also by compression, especially if care be taken to put it in the posterior *cul de sac* of the vagina. It suffices to apply one plug a week, and should not be left in longer than twenty-four hours, after which all the alum is dissolved, and the plug becomes a foreign body, which should be withdrawn. The withdrawal effected, the local treatment is limited to the injection three or four times a day of water, as warm as the patient can support.

In uterine hæmorrhage the same Dr. Després uses strong coffee, of which he makes his patients take four or five cups daily. He attributes to it properties analogous to those of ergot, and employs it under the same conditions.

The intense fog that enveloped the city last week has greatly increased the number of chest affections. *La Grippe* has been particularly rife, due in a great part to the sudden rise of temperature. Accidents resulting from the *brouillard* have been very numerous and serious. In one case a woman was run over by a heavy vehicle, and when she was carried to a chemist's it was found that one of her legs was missing! She expired almost immediately. The leg, which was completely cut off a little below the knee, was found lying in the street where she was run over.

◆

# Department of Lunacy.

## PROPOSED NEW LUNATIC ASYLUM.

AT a meeting of the Exeter Town Council on Thursday last, it was decided to erect a new Lunatic Asylum, there being in other parts of the county over 100 lunatics who belong to the city, and whose maintenance annually takes from £3,000 to £4,000 out of Exeter. Authority was given for the purchase of 66 acres of land near the Woodbury Common, a locality specially recommended on account of its healthy situation. The cost of the land will be £2,150, a much lower sum than had been anticipated for so large a site. The building to be erected is expected to cost over £50,000.

◆

## SURGICAL OPERATIONS ON THE INSANE.

AT a recent meeting of the Paris *Société de Chirurgie*, M. Pozzi brought forward two cases in which severe surgical operations had been performed on insane patients. The first was a case of necrosis of three metetarsal bones, and Lisfranc's amputation was performed with removal of the first cuneiform bone. Cure and cicatrisation took place without complication. The second patient, a general paralytic, was affected with gangrene of the foot; the general condition being very bad, œdema, cachexia, &c. Dr. Pozzi performed amputation above the malleoli, which succeeded perfectly, the patient regaining the comparatively healthy condition he had previously enjoyed. These two cases prove to M. Pozzi that mental alienation, and even a chachectic condition, are not contra-indications for surgical interference, these patients being as susceptible of cure as others.

◆

## EDINBURGH ROYAL ASYLUM FOR THE INSANE.

THE annual meeting of the Corporation of this Institution was held in the Council Chamber last week, Lord Provost Boyd in the chair.—Mr. Scott Moncrieff, W.S., secretary, read the report of the managers for the past year, which stated that the gross daily average number of patients under treatment in all departments was 812, being an increase of 36 over the number of last year. The ordinary income for the year was £39,696 6s. 3d., and the expenditure, including instalments to the sinking fund, £35,621 13s. 7d., leaving a surplus revenue of £4,074 12s. 3d. The indebtedness of the asylum at the 21st December, 1878, was £50,204 7s. 1d., and at the same date in 1879 it amounted to £47,215 15s. 6d., showing a decrease of debt of £2,988 11s. 7d. There was a marked increase in the number of patients paying the higher rates of board, which was mainly attributable to the additional accommodation afforded for such patients in the mansion of Craighouse. As the proposed Edinburgh Suburban and South-Side Railway would pass through the grounds in such a direction as to cut off the estate of Craighouse from the rest of the property, the managers and medical board were of opinion that it would inflict serious injury upon the asylum property, and might injuriously affect the patients, and they had resolved to oppose the bill in Parliament. The Charity Fund accounts showed that the income during the year had been £445 13s., and the expenditure £518 19s. 1d. The fund now amounted to £9,487 16s. 3d. The number of patients on whose accounts allowances were made during the year was 48, and the average allowance to each £10 16s. 2d.—The Lord Provost said it was exceedingly gratifying to the managers to be able to present so gratifying and satisfactory a report. He had much pleasure in moving that the report be approved of, and the accounts remitted to the auditor in the usual way.—The motion was adopted.

◆

# Transactions of Societies.

## CLINICAL SOCIETY OF LONDON.

The last meeting of the Clinical Society of London was held on Friday evening, Feb. 27, the President, Dr. E. Headlam Greenhow, in the chair.

Mr. **Teevan** related the particulars of

### A CASE OF RETENTION OF URINE FROM A CALCULUS IMPACTED IN THE MEMBRANOUS URETHRA, RELIEVED BY PUSHING BACK THE STONE INTO THE BLADDER WITH A WAX BOUGIE AND CRUSHING IT.

He stated that it had always been his practice when a calculus was impacted in the deeper portion of the urethra to try and push it back with a wax bougie into the bladder, and there to crush it. It appeared from a perusal of English works on surgery that the above practice, so well known in Paris, was unknown here. The recommendation in English books to push back the calculus with a silver catheter generally failed, as the opposed surfaces of the stone and catheter were usually convex, hence the cathether, instead of pressing against the calculus, attempted to pass by it, thus driving the stone into the wall of the urethra. Even if the catheter was truncated it was not more useful, for the surface of the calculus was usually irregularly convex, so that it did not fit into the end of the instrument, and thus it was that no efficient pressure could be made. A wax bougie, however, fulfilled all indications. If it were slightly warmed before using it, and one end curved, it would, when arrested by the stone, become accurately moulded and fitted to the surface of the calculus, so that the two bodies virtually became one, and the surgeon could exercise gentle, firm, and efficient pressure.

Dr. **Buzzard** read a paper on

### A CASE OF PARAPLEGIA FROM POTT'S DISEASE, TREATED BY SAYRE'S SPLINT; INTESTINAL OBSTRUCTION—DEATH FROM A KINK IN THE DUODENUM.

The patient was a labourer, æt. 22, employed in carrying heavy sacks, who, after suffering from pain in the back, lost the use of his legs in December, 1878, and was admitted into the National Hospital for the Paralysed and Epileptic, under Dr. Buzzard's care, in April, 1879. On examination it was found that in the mid-dorsal region there was an angular curvature, of which the sixth dorsal spine formed the apex, the curve extending from the fourth to the tenth dorsal vertebra. There was absolute paraplegia, with anæsthesia, of all parts below a line encircling the body two inches beneath the nipples, and incontinence of dejectum. On April 24th the patient was slung, and Sayre's plaster jacket applied. This was found to be comfortable. On April 30th, after indulging freely in dough pudding the patient was seized with discomfort and vomiting, on account of which, as an ordinary enema failed to produce relief, the plaster casing was removed. There was abdominal distension with tenderness, especially in the epigastric region, and percussion appeared to show that the stomach was distended. Morphia and atropine were employed hypodermically, but the symptoms of obstruction continued, and death took place after they had lasted only sixty-eight hours. The vomiting was never fæcal in character. Autopsy showed the spinal dura mater thickened and adherent to the anterior wall of the canal in the region of the curvature, where the bodies of two vertebræ were disintegrated, and abscesses corresponding to them were found about the column when the chest was opened. The cord was bent upon itself at an angle of 125° and at this part had lost its natural firmness. Microscopically, evidence of diffuse myelitis was discovered, with secondary degenerations, extending to either extremity. On opening the belly, the stomach and duodenum were found enormously dilated, and the last part of the duodenum folded down upon itself, the whole intestinal canal below this point being contracted and containing scybala. Dr. Buzzard remarked that the origin of the disease was clearly traumatic, the cause being, as in the case of another patient of his at the same time in hospital, the carrying of heavy sacks. This accorded with Dr. Sayre's experience as to the etiology of Pott's disease. The object sought in employing the splint was that the patient might enjoy the best possible condition for ankylosis without the necessity of keeping his bed, and it was carefully and skilfully applied. The point of special interest was with regard to the question whether the casing had conduced to the kink in the bowel. The situation of the latter was uncommon, and attributable to interference with the natural peristalsis. With so complete a paraplegia the innervation of the intestines was probably to some extent troubled, and it was conceivable that when the ribs were fixed and the stomach distended, the jejunum might easily, during the descent of the diaphragm in inspiration, get forced downwards, and thereby bent upon the duodenum, which was not free to move on account of its attachments. The peristaltic action which was necessary for the unfolding of the gut might be either deficient or unable to be exerted successfully from the relations of the parts to the rigid casing which embraced the abdomen as well as the chest. Dr. Buzzard reserved his opinion as to whether or not this had happened in the present instance, but he thought it important to put the case on record. The incident, of course, may have been a simple coincidence. He referred to a case published by Mr. Willett in the 14th vol. of St. Bartholomew's Hospital Reports, in which fatal vomiting followed the application of the plaster-of-Paris bandage in a case of spinal curvature. The stomach in that case, as in this, was found enormously dilated, but, further, it was thought also to show evidences of old disease, and it did not appear that any obstruction in the intestinal canal had been discovered. As regards the obstruction in the present instance, Dr. Buzzard remarked that its nature would have peculiarly fitted the case for operative interference, but he left it to the surgeons to say whether its position (at the third portion of the duodenum) would have proved or not a bar to successful gastrotomy.

The **President** inquired whether Dr. Buzzard was able to ascribe the injury to his patient to any particular occasion. It is difficult, he explained, to imagine that so considerable an amount of spinal curvature could be produced by a cause so simple as that described in the paper. Also he wished to know if sections of the cord had been made. Such sections would be of the greatest value.

Dr. **Duckworth** asked if the intestine had been opened *post mortem*, since it might have exhibited considerable and instructive change. He had, more than once, been compelled to remove the plaster bandages soon after application.

Mr. **Heath** was of opinion that the injury was not correctly described as a kink of the duodenum, since it really was in the jejunum; and it is, he continued, a well-known fact that this point of the intestine, close to the mesenteric artery, is excessively liable to injury by tearing, &c. For this there is a mechanical reason, the duodenum being firmly attached, while from it depend the freely movable intestines; consequently a very small cause might determine a fold in this situation. He could not agree that the pressure on the body produced by the jacket would suffice of itself, since in women the continuously-maintained pressure on the ribs with stays would then be an equally productive source of danger. He believed that an internal abscess *always* accompanies caries of the spine. Many, he admitted, denied this, and he was glad to find Dr. Buzzard's case supported his belief.

Mr. **Marsh** did not think that the scrofulous diathesis should be entirely omitted from the list of causes predisposing to spinal disease. The injury must necessarily be as great, when traumatic, in a scrofulous, as in a healthy patient; and surgeons generally agree that Sayre is wrong, and that some constitutional defect is at the bottom of disease of this kind. He thought that in dealing with cases of intestinal obstruction time ought never to be lost, the safety with which an operation can be performed, as well as the danger incurred by delay, serving to indicate its early performance. He had recently been called to see a case of supposed strangulated hernia. It turned out not to be this, but an easily-removed intra-abdominal obstruction. Though the patient died eventually of pyæmia, he considered the case tended to prove the ease and security with which operations of this kind can be performed. He was almost certain that death occurred through the patient being placed next another one suffering from blood poison. He thought morphia only masked the symptoms of disease, and wondered that Dr. Buzzard prescribed it. Concerning the tightness with which the bandage fits, much misconception, said Mr. Marsh, exists. In the majority of cases as much as ⅛th of an inch of space separates it from the body, and the introduction of the dinner pad is another security against compression of the body-walls. He would be sorry to imagine that there had been described a *new* danger in the treatment of those cases arising out of interference with the intestinal functions.

Dr. Duffin mentioned a case recently seen by him; it was that of a Post-office official, who presented an angular curvature involving the ninth, tenth, and eleventh dorsal vertebræ. The pressure on the cord produced considerable paraplegia, there was little motor power, the loss of sensation was only small, and reflex action was well preserved. The angle was very marked. Sayre's jacket was applied, and the patient kept in bed. When the bandage was removed, he cut a hole successively over different points, and applied thereto the actual cautery, repeating the treatment with much success. When patient left the hospital, he could walk easily as far as three miles at a stretch, and experienced no distress on pressure of the spine. He thought much of the good done by treatment is due to the varying methods adopted.

Mr. Barker said that by pressing on the dura mater, the abscess could produce an influence on the cord through it. He thought that during the fitting on of the plaster casing, the body being straightened, the thorax is really disturbed, and pressure on the abdomen is relieved. The thorax subsequently shrinks, and leaves ample room for the respiratory movements. Another point not considered is the fact that the thorax has the form of an inverted cone, and the shape of the complete casing of plaster bandages is that of two inverted cones meeting by their apices. He did not think the functions of the bowel were in any way interfered with by the casing.

Mr. R. W. Parker inquired whether the paraplegia preceded or followed the adjustment of the jacket.

Mr. Barker added that he made a post-mortem examination of the first case which Prof. Sayre treated in this country. The patient died of pneumonia, and an abscess similar to that described by Dr. Buzzard as found in his case was discovered.

Dr. S. Coupland thought it desirable to operate early in cases of acute intestinal obstruction. The difficulty of accurate diagnosis of the point of obstruction he judged to be the sole cause of such delays as do occur.

Dr. Walsham said he had recently made some experiments to determine whether the hand could trace the direction in which it was exploring when proceeding along the intestine. He came to the conclusion that it could not be mistaken when going towards the duodenum. He believed the disease originates in the joints, and not the substance of the bone.

Mr. Howard Marsh did not agree with Mr. Barker's description of the state of the thorax, which he (Mr. Marsh) thought is really drawn down during suspension of the patient. From this it should follow that on being released from the apparatus of support, the bandage would be perceptibly tighter; and that such is the case is a common experience.

Mr. Barker explained that in his description he assumed the patient to be suspended not by the head alone, but with the support afforded by the arm slings ordinarily employed.

Dr. De Haviland Hall mentioned a case in which a patient died through rupture of the ileum, which was preceded by the descent into it of a large gall-stone.

A visitor said he had recently seen a case under treatment by Mr. Golding Bird which tended to prove that spinal disease might originate traumatically. The patient dated the affection from the time of receiving an injury, angular curvature following recovery. He (the speaker) had witnessed instances of intestinal obstruction caused by food in the horse, the duodenum being directly implicated.

Dr. Buzzard in replying on the points raised during the discussion of his paper, said microscopic sections of the cord had been made, and marked sclerosis was present in it. There was much hypertrophy of connective tissue, and general overgrowth. At the point where the cord was softened there were many important changes noted. The axis-cylinders were few, but there were numerous vacuous and medullary fibres, and the appearance of transverse interstitial myelitis involving the lateral and posterior columns. There was no history of traumatism, of scrofula, or phthisis. The subject was a healthy man, in whom the pain in his back had come on gradually, forcing him eventually to keep his bed. At the same time, said Dr. Buzzard, as he was treating this case, he had another patient under observation. He, likewise, was a healthy labourer, accustomed to lifting heavy sacks. Both cases went to confirm Sayre's views. In many cases it is admitted that violence precedes symptoms of disease. In the case reported to the Society, the point at which the gut was folded presented no ulcer, or other pathological change, except a hyperæmic condition of the parts. He noticed that four out of twenty-two men required the removal of the plaster-jacket within twenty-four hours of its application. He thought the delayed operation for intestinal obstruction justified by the conditions. It was not unreasonable to suppose that the obstruction arose from the food previously taken in such quantity. This had happened over and over again, and by a little waiting the interference had been removed. In making the post-mortem examination, the spinal canal was first opened, and the pus found was excessively inspissated. The patient was treated on account of paraplegia, which, therefore, preceded the application of the jacket.

Dr. Sangster read notes on a case of

### MOLLUSCUM FIBROSUM.

of which the following is an abstract:—The patient, J. S., æt. 50, was small in stature, but by no means stunted or ill-developed. There was nothing of interest in his family history. One of his children was said to have been born with a tumour on the penis similar to those on the patient's body. The first tumour appeared on the patient when he was 23 years old. According to his statement—one which can scarcely be credited—his body was covered at the expiration of a year from the appearance of the first tumour. The face had been attacked more recently. The trunk was most affected, hundreds of molluscum tumours being seen in front and behind. They presented the usual diversity as to size, shape, mode of attachment, &c.; some were so closely packed that their opposed surfaces were flattened. They appeared to congregate especially round the nipples and in the grooves between the erector spinæ muscles. The extremities were affected in a lesser degree. The scalp presented many tumours; and, a point of great interest, there were tumours on the right sole and palm. One tumour was pendulous and flaccid, as large as a small orange; it felt like a varicocele. The skin everywhere was dusky and muddy-looking; there was clearly much disturbance of pigment, brown vascular patches of all sizes being scattered over the surface. A small tumour was noticed on the hard palate behind the central incisors. Variously sized tumours were excised for examination, together with some minute papular elevations with comedo-like orifices, which appeared to be the earliest lesions. Dr. Sangster added that the comedo-like spots are easily recognised. On pushing the skin about the tumour, it puckers up, thus indicating its deep origin. The Germans averred that the sebaceous glands are not involved, but he (Dr. Sangster) thought the microscopic sections he exhibited would prove that these structures are not inert during the production of the diseased growth. The patient shown before the Society had some of these tumours on the plantar surface of the foot, and this led him to think that the growths are connected with both the glands and the skin.

Mr. George Brown exhibited a fresh specimen, consisting of an intra-pelvic tumour of about fourteen months' duration, removed from a boy (during post-mortem examination) aged fourteen years. Mr. Brown will read a paper on the case at a later date. The tumour presented encephaloid characters.

◆

At the annual election of Fellows into the Council of the Royal College of Surgeons of England there will be at least three absolute vacancies. Messrs. Busk and Curling have definitely declined to be put in nomination for re-election, and the death of Mr. Hancock throws another seat at the disposal of the Fellows.

## THE EFFECT OF ALCOHOL UPON THE LIVER.

THE recent trial of Lewis Paine for procuring the death of Miss Maclean by encouraging her to drink ardent spirits, and at the same time neglecting to supply her with proper and sufficient food, has attracted a great deal of attention. It has long been a generally recognised fact that indulgence in spirits, and especially when only slightly diluted, or what is known as "raw" spirit, induces enlargement of the liver. Whether this enlargement passes onwards to subsequent contraction and diminution, the normal history of cirrhosis, in all cases may be questioned. That such ulterior diminution of the bulk of the liver is found with chronic drunkards is certain enough; but how far the liver can reach the cirrhotic stage in cases of acute alcoholism we do not yet very definitely know. From the history of the case given above this would seem probable. It would appear that in April last Miss Maclean was in her usual health. In the middle of September Dr. Beadles was consulted as to whether she was pregnant or not. Whether this impression of pregnancy was caused by abdominal enlargement or not is scarcely quite clear from the evidence. But it seems probable. About the same time, a day or two before, Mr. Shepherd, of Worcester, saw her, and found her to be suffering from a large abdomen—"flatulent distension of the abdomen." There is at this time no statement as to any enlargement of the liver, Mr. Shepherd believing that the liver was "congested." On the 6th of November Mr. Waller, of Upper Dorset Street, was called in, and found "the liver was very hard and enlarged, and prominent to the touch." On the 20th of November Dr. Spurgin made a post-mortem examination on the poor lady, and found the liver enlarged. It weighed 60 ounces. Gray gives the weight of the liver as from 50 to 60 ounces. Now, granting that Miss Maclean was diminutive in stature, this was not because she was so *petite*, but because she had short lower extremities and a spinal curvature; her liver was but little more in weight at the time of her death than her liver would normally be in health. Yet only a fortnight before the liver was enlarged and prominent to the touch, as well as abnormally hard. Now if we are to accept this medical testimony, and there is nothing of a doubtful character about it, the conclusion which is suggested is—that under the free use of ardent spirits Miss Maclean's liver, which was of normal size on the 16th of September, when seen by Mr. Shepherd, and on the 20th, when seen by Dr. Beadles, had become distinctly enlarged by the 6th of November; and that on the 20th of that month it was found enlarged, but not to any very abnormal extent, i.e., to the weight of a normal liver in a man. Not only was there evidence of the liver being organically changed, but the structure of the heart was in an early stage of fatty degeneration. We are quite familiar with the rapidity with which tissue degeneration is set up by alcohol; but this is a terribly instructive lesson. Here we have a comparatively young woman who, though deformed, was not diseased, and whose habits, though irregular, did not extend to distinct intoxication, at the commencement of April is in apparently perfect health; and yet on the 17th of November of the same year she dies with well-marked degenerative changes in her viscera.

Now Murchison says that in the early stage the symptoms are those of alcoholic dyspepsia; a craving for alcohol, loss of appetite for solid food, and furred tongue, depression of spirits, &c., often with flatulence. In the second stage "there is progressive emaciation and debility. In consequence of the obstruction of the portal vein the intestinal absorption of nutritive material is diminished and then suspended, while the blood-forming functions of the liver and spleen are more or less impaired. In many cases the patient dies by exhaustion, the intellectual faculties remaining clear to the last." It appears that on the last morning visit paid to her by Dr. Thorman she complained of shortness of breath, and was in so far rational. As to gastric inflammation from drinking ardent spirits, it was not found in this case; and doubtless Dr. Spurgin was correct in saying that the stomach might have recovered itself in the last few days of life when she was not taking other than highly diluted spirits. In his opinion Miss Maclean died of syncope of the weakened heart.

Here, then, we have a distinct history of liver change, and death from exhaustion in a period of certainly not more than six months under the effect of acute alcoholism. From a condition of perfect health, as regards the organs and tissues of the body, death with well-marked degenerative changes is reached in this brief period. We are compelled to regard this as an instance of very rapid downward changes, and the rapidity of the changes teaches two lessons. One, a pathological lesson, is this: that the tissues of some persons deteriorate much more swiftly under alcoholism than do those of others. Just as the intellectual and moral changes differ in the time of their production, under alcoholism, so do the organic changes in the viscera. It is well-known that when comparatively young women "take to drinking," their course is usually a very brief one. Especially is this the case where enlargement of the liver is a conspicuous symptom; and where this is found the most active measures should be taken to remove the patient from any possible access to spirits. Then there is a second lesson: a moral one as well as a clinically interesting one. An unfortunate deformed girl, with strong passions, forms an attachment to a scoundrel; at the same time that she developes a liking for stimulants. On the death of her mother she becomes her own mistress, and he induces her to cohabit with him. By doing so she forfeits her position in society and alienates her friends. Having got his prey into his clutches, her paramour encourages her to drink. Under this isolation and intemperance combined he succeeds in depriving her of her property. Now, however defective Miss Maclean's moral sense may have been, we have no evidence of intellectual incapacity in her. Seduced, indeed living in open shame, robbed, conscious of being deceived, no wonder then that the craving for ardent spirits was strong! It needed no fomenting, probably. The progress of her liver disease was remarkably swift. We now know something of the effect of mental worry in the production of visceral mischief. Not only did the unfortunate creature drink heavily, but her mental distress must have been extreme, so that the loss of appetite and craving for spirits was intensified by mental worry. Such being the case it was comparatively easy for her paramour to develope the natural craving. Under these circumstances, then, we can readily understand the rapidity with which the morbid changes in the liver advanced.

## THE NEW VICTORIA UNIVERSITY.

With an absence of pomp and circumstance, which may be regarded as characteristic of the plain and practical North, Owens College has at length obtained its charter, and Victoria University is an established fact. In hastening to proffer our best wishes for the future career of this interesting stranger, we note but one rock ahead, which threatens to give us a repetition of the fate of Durham; we mean, of course, the absence of medicine and surgery from the degree-granting power of the University, and can only hope that the name of William Bowman, among the list of its rulers, may foreshadow a near removal of this serious blemish.

The Owens College, it is needless to say, would have sued in vain for its charter without the aid of its medical school; and it seems but a poor return for all the College has gained by the union with the proprietary school of the late Messrs. Turner and Southam that this large department should be the only one to profit nothing by the charter.

The very *raison d'être* of the University, in a great measure is its medical school; and were this elevated along with the rest of the College, we should have a centre of intellectual activity which would act as a most healthy protest against the centralisation of London and Edinburgh; so that we might confidently look for more and better original work, just as the smaller German Universities, which have become such formidable though friendly rivals of the great schools of Berlin or Vienna, year by year turn out abundant work of the very first quality. Doubtless the failure is only temporary, for we may expect the opposition led by Liverpool will not be repeated when more liberal terms are offered to this important neighbour, and a little more tact is imported into the mutual negotiations. Much stress is laid upon the fact that Liverpool is a proprietary school of medicine, and cannot therefore be affiliated; it is more than questionable whether the *therefore* is a logical *sequitur* in the case at all; red tape may see difficulties in the simplest things, but these are not matters to stop common sense. The common sense as well as politic step is to accept attendance on all the classses at Liverpool as equivalent to attendance upon similar classes in Owens College; and if this were granted we have reason to believe that Liverpool would be perfectly satisfied with the terms, and would consent to send her students to those classes not at present represented in her own school, until she had followed the lead of Manchester and Leeds, and established classes in arts and science for herself. The same terms should be offered to Sheffield.

In regard to Leeds no difficulty exists: there is already the Yorkshire College of Science, and though it is not yet amalgamated with the School of Medicine, this amalgamation will probably shortly take place, when Leeds may be affiliated to the University on perfectly equal terms with Owens College, less the fact that the examination will take place in Manchester.

Meanwhile it is the clear duty not only of the medical profession outside, but of the medical portion of the Senate, to urge the claims of medicine to recognition. At present the Colleges have gained everything from the amalgamation with the Medical School; the School, on the other hand, has lost as much as it has gained, for while it has obtained access to admirable physiological and chemical laboratories, it is sore let and hindered by having to tramp a mile and a quarter from the hospital to their laboratories. So great indeed is the inconvenience and trouble caused by the long distance which lies between the Infirmary and the College, that it may well be considered the duty of the College to obtain premises close to the hospital, where the lectures, except those on anatomy, physiology, and chemistry, might be delivered, with an ulterior view of enlarging the premises so as to accommodate all the classes, including those which at present might be excluded.

It is generally agreed that the medical and surgical degrees should, if granted, be purely decorative, and should in no case be conferred until the candidate was entitled to practise by having passed some examining and licensing body, so that the recognition of medicine and surgery in the Victoria University would not in the smallest degree interfere with, or oppose, the creation of the single portal system.

## THE IRISH PRISON SURGEONS.

As the disputes which have arisen between the surgeons to prisons in Ireland and the department under which they act, have now extended over two years and four months, and the references in our columns to the circumstances of those disputes have been necessarily somewhat desultory, we may with advantage recapitulate the facts of the controversy from first to last. On the 1st of April, 1878, the Prisons (Ireland) Act came into force, and thereupon the office of Inspectors of Prisons was abolished and a new General Prisons Board was invested with the entire control of gaols in Ireland. Previous to the passing of this Act the office of medical officer to an Irish county prison had been, as a matter of law, held by the surgeon to the County Infirmary, who received a certain salary from the grand jury as the Infirmary Surgeon, but on condition that he presented a certificate that he had efficiently discharged the duties of the prison. This tie between the Infirmary and the Prison being dissolved by the Prisons Act, it became necessary to provide separately for the medical care of the gaol, and accordingly the clause of which the following is a faithful abstract, was embodied in the Act :—

> The officers atttached to prisons on April 1, 1878, shall hold their offices by the same tenure, and upon like terms and conditions, as if this Act had not passed, and shall receive salaries of not less amount than those which they have hitherto received.
>
> Such existing officers as aforesaid (except medical officers, apothecaries, &c.) may be distributed amongst the several prisons, and all such officers shall perform such duties as they may be required to perform by the said General Prisons Board, so that such duties are the same or analogous to those they performed previously to the commencement of this Act, and, subject as aforesaid, they shall perform the same duties as nearly as may be as they shall be performing at the same date.
>
> From and after 1st April, 1878, no surgeon of the infirmary of any county shall be bound or required as a condition precedent to the making of any presentment for his salary as such surgeon under the provisions of sec. 86 of 6 & 7 Wm. IV., cap. 116, to give his attendance or assistance to the prisoners or others in the gaol of such county.

It will be observed that this section bound "the officers *attached* to prisons" to perform duties the same or analogous to those "they performed previously to" April 1, 1878, and "the same duties as nearly as may be, as they shall be performing at same date." Notwithstanding this provision, the first Act of the General Prisons Board was to superadd a number of new duties, which nearly trebled the work of the surgeon; their next proceeding was, in direct violation of the clause, to dismiss the apothecaries (who were to "hold their offices by the same tenure as if this Act had not passed") and to require the surgeons to dispense the medicines, a duty which they had never been charged with before, and which most of them felt themselves incompetent to perform. To these impositions, which were, and are, plainly a violation of the spirit of the Act, the medical officers of prisons objected, as being illegal and unjust, and they received for reply an intimation that they must elect between performing the additional duties or being dismissed.

This audacious attempt to break the law which they were appointed to administer, the General Prisons Board tried to justify by asserting that the surgeons were not, within the words of the clause, "officers attached to prisons," inasmuch as they were infirmary surgeons performing the prison duty, so to speak, into their bargain. Such an interpretation of the words of the Act was plainly an evasion of the intention of the Legislature which passed it—for this the Prisons Board cared nothing—but it was also obviously a malversion of the law, and was declared positively so to be by Mr. Purcell, Q.C., who was consulted by the Irish Medical Association thereupon. So far did the Irish Prisons Board push this quibble of theirs, that they actually refused to pay the salary of a medical officer who was tortured into resigning his office after nine months' service under the Board. And not only has not that salary been paid, but not a sixpence has been paid to a single prison medical officer in Ireland for this two years of duty since April, 1878. Up to this period of the controversy, the General Prisons Board had confined itself to imposing illegal duties, and attempting illegal dismissals. It remained for it to complete the transaction by fixing illegal salaries, and attempting to "do" the surgeons out of the rights reserved to them by the law. The Board after some little time, promulgated an order, fixing the salaries at £80, £60, and £40 a-year for the three classes of prisons; these amounts being, in most cases, a considerable curtailment of the emoluments previously received in consideration of the prison work, and this curtailment was proposed, despite the imposition of many onerous duties not at all authorised by the Act. Such salaries the prison surgeons positively refused to accept, and, if it had been necessary, they would, doubtless, have fallen back upon the Court of Queen's Bench to defend their rights. Seeing the probability of this course, and of a discreditable exposure before the public if they persisted in their despotic course, the Prisons Board gave in, and covered their retreat with a "Departmental Committee" charged, no doubt, with the task of planning a decent escape of the Board from the opprobrium of its previous proceedings.

That Committee reported a couple of weeks since, and recommended salaries of £200, £100, and £60 respectively, for the three classes of prisons, being nearly three times the amount which the Board had previously thought to force upon the medical officers. In pursuance of this report the following letter has been addressed to the surgeons :—

> Dublin Castle, 18th February, 1880.
>
> SIR,—I am directed by the General Prisons Board to inform you that the Treasury have sanctioned the payment of a salary of £—— a-year from the 1st April, 1879, to the surgeon of —— Prison, on the condition that he shall compound all medicines prescribed by him for the inmates and officers of the prison.
>
> The Lords of the Treasury have also laid down the following rule, viz., That in every case in which existing medical officers do not compound the medicines prescribed by themselves a reduction of £20 per cent. will be made from their salaries.
>
> You are aware that a salary of —— was sanctioned for the surgeoncy of —— Prison for the year 1878-79, on the condition that that officer compound his own prescriptions, but the question is still under consideration whether any abatement is to be made from such salary consequent on your not compounding during that time.
>
> You are requested to reply to this communication at your earliest convenience.
>
> I am, Sir, Your obedient servant,
>
> RICHARD CLEGG, Chief Clerk.

On careful perusal of this letter two points present themselves—

1. That surgeons are to be fined £20 a-year if they refuse to compound.

2. That they are to be paid for the year 1878 the salary originally proposed and repudiated by them.

We have given reasons above for our certainty that the Board has no legal power whatever to superadd compounding to the surgeon's duty, and the Board seems to be quite conscious that it never had any such power and that the surgeon may, if he pleases, refuse absolutely to dispense his medicines.

It seems likely, however, that most of the prison surgeons, while feeling that the Board has meanly taken advantage of them, will accept the terms offered to them.

The second proposition of the Board, that they shall pay for the year 1878-9 a much less salary than for the year '79-80, is clearly untenable, and were we not accustomed to the aberrations of public departments, we should be surprised that the Board should advance such a suggestion. It pleased the Board, in flagrant violation of the law, to lay down its own scale of payments. That scale was at once vehemently repudiated and scorned by the medical officers, and it was not confirmed by the offer or the acceptance of a single payment, and now the Board seeks, while fixing the value of a doctor's services in 1879 at a given amount, to assess, by its own mere motion, the value of the self-same services in 1878 at about one-third of that amount. The proposal is as ridiculous as it is illegal, and we venture to believe it will not be countenanced for a moment by Parliament.

We cannot leave the subject without pointing to the action of the Prisons Board in the whole affair as a very unedifying spectacle but a very useful warning. How much of its proceedings we ought to credit to its own intrinsic despotism and disregard for justice, and how much to the meanness of the Treasury in the granting of money for Irish purposes, we cannot judge; but we cannot hesitate to express our astonishment and disgust that a public department should condescend to attempt to bully its officers out of rights which they always possessed, and which Parliament confirmed to them. We regret to observe that it has become the fashion in Government departments to "try on" how much they may encroach upon legal rights and vested interests, and, when met by a vigorous opposition, to retreat ignominiously and fall back upon the law. In the business of a private commercial firm it is not considered reputable to offer five shillings in the pound on an honest debt to a creditor, on certain conditions, and then, when met with refusal, to pay at once twenty shillings in the pound without any conditions, and we do not think that the public service of the country can long maintain the respect due to it if it adopts such a course.

◆

## THE SUPERVISION OF PRIVATE EXECUTIONS.

A good deal of dissatisfaction has been felt of late with the manner in which executions have been conducted, and especially with the growing practice of excluding reporters from them, by which privacy is being converted into secrecy. A new departure in the art of occult hanging has just been made at Manchester, where the governor of the Strangeways Prison declined to admit reporters to the gaol in order that they might be present at the inquest on the body of William Cassidy, who was executed there on the 17th ult. The coroner very properly resented this attempt to interfere with the privileges of his court, and held the inquest at a neighbouring hotel, where the jury made a presentment, which has since been forwarded to the Home Secretary, in favour of reporters being admitted to executions. The public will, we believe, agree with the jury, and demand that the objectionable regulations of a testy and timid officialism be rescinded forthwith. While shop windows in our leading thoroughfares exhibit the *Illustrated Police News*, and while the literature of crime still circulates freely, it is foolish to argue that such temperate descriptions of executions as are likely to find their way into the columns of our respectable newspapers will brutalise the masses or inflame evil tendencies. A punishment which cannot bear to be described is not fit to be inflicted, and capital punishment is itself at its last gasp if it can only be carried out when shrouded in mystery. Even if the sketches of the reporters were proved to be prejudicial to public morals, we should have to encounter that evil rather than the far graver evil involved in any distrust of the machinery entrusted with the consummation of judicial penalties, and the current of sympathy which would consequently flow towards our criminal classes. The public has a right to require a trustworthy assurance that capital sentences are decently and humanely carried out, and that assurance they cannot have save by the testimony of their own direct representatives in addition to that of paid officials. We have nothing to say against the officers of our prisons. Doubtless they are all efficient, kind-hearted, honourable men, but their evidence on a matter falling within their sphere of duty can never be absolutely above reproach, because they see through official spectacles which have a curious practice of growing dim, unless constantly polished by extraneous friction. Hence the necessity for having vigilant, clear-eyed, and open-eared reporters present at executions. Even their presence will not always secure propriety and merciful care, for we have just heard of the public execution in Canada of a wretched Indian, called Swift Runner, which was conducted with scandalous negligence. The miserable man had to wait in sight of the gallows while they were being repaired, and when everything else was ready, his death was again delayed because the nervous executioner had forgotten a strap with which to bind his arms and legs. No wonder that he offered to cut short suspense by braining himself with his own tomahawk. But this was not permitted, and so he ate some pemican with the noose round his neck while the strap was being fetched, and was at last thrown off while his own people performed the death-dance around him, and expressing his disbelief in the God of the white man, who had ruined him with whisky and hanged him so lamely. Atrocities of this kind are not likely to be perpetrated in our midst; but still very painful scenes have occurred at executions in this country within a recent period, and of course no one knows what may have taken place at executions of which no account has been given beyond the hoisting of a black flag. In our view, not only should reporters be present at executions, but an independent medical man also, appointed by the coroner, to witness the execution and the post-mortem examination afterwards. The coroner and his jury would then have unimpeachable evidence as to whether the execution was conducted in a humane and scientific manner, and as to the immediate cause of death. The evidence of the prison surgeon would of course be heard also, but that can never have the value of the testimony of a medical man of good standing in general practice drawing no salary from the prison department, and in no way under its authority.

## THE ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

At the annual meeting of the Association of Surgeons practising Dental Surgery, held on February 18th, the President, Mr. W. A. N. Cattlin, F.R.C.S., delivered an address dealing chiefly with the position in which the dentists stand with respect to the general profession. He briefly sketched the progress of the dental surgeon in the past, and attributed a very great amount of the advance made in the professional status of the dentist to the action of the Odontological Society, assisted, as this has been in its attempts at elevation, by the other dental associations and colleges. He expressed an opinion that "the amount of scientific knowledge which dental surgeons have contributed to the general stock of literature will bear favourable comparison with any other specialty," and continued—"All was proceeding well with dentistry until the Dentists' Act of 1878 fell, like a withering stone, and cut us off from the parent tree." Mr. Cattlin then proceeds to consider by what means this unfortunate evil is to be met, and emphatically declares his conviction that the separation of dentistry from surgery, as is practically done by the Dental Register, is "an error of the highest magnitude." The whole gist of the matter is undoubtedly contained in this particular. That it has been an unwise proceeding on the part of dentists to transform themselves into a body of pure specialists, most people are ready to admit; and this the more especially as through it the way is opened to pretentious aspirants who would otherwise be shut off from a pursuit to which they do not bring the essential qualities of the general practitioner. Since it is true, as asserted by Mr. Cattlin, that out of 5,289 names which appear in the Dental Register, no more than 532 have given positive evidence of either a medical or dental education, the simple fact is a sufficient proof of the unsatisfactory state in which this branch of the profession is placed. In the way of amending the situation, a suggestion is made that under the proposed conjoint scheme a candidate may be at liberty to notify his desire to be examined as to efficiency in a special branch of surgery, subsequently to his successfully passing the common qualifying test. He should then, if he show a satisfactory acquaintance with the selected specialty, dental surgery being one, receive a testimonial to that effect, and, thus provided, he would be in a position to practise as a specialist, with all the advantages derivable from a proper general knowledge of his profession. The sound wisdom of this proposal will commend it to every one anxious to see the new departure in education that will follow the passing of the Medical Acts Amendment Bill productive of practical benefits, and the young Association of Dental Surgeons is to be congratulated on the admirable perspicacity with which they regard the anomalous position they at present occupy; and further, too, on the firm determination they show of doing their utmost to remove the reproaches that cling to their order as a body.

With the disagreement between the presidents of rival societies we have no particular concern, but we can hardly refrain from the thought that the reproach of which Mr. Cattlin complains, viz., that "they who had the power to carry the Dentists' Act have also the power to maintain it," seems not entirely undeserved. His straightforward admission of error, however, disarms his opponents, and his frank suggestion that the action taken, apparently in ignorance of the fatal results it has borne for fruit, shall be amended by retracing the wandering steps that have led the dentist from the mother tree, will be approved by all right-minded people, whatever the view they originally held on the matter. He insists that the amendment shall be speedy and complete, and adds, "All qualified practitioners now on the Dental Register I would carry as fast as I could to the Medical Register, and for the future adopt the scheme suggested" (that of special certificates, under the conjoint examining board).

We welcome the liberal spirit of reform indicated by the address, and congratulate the Association on the steps it is taking to advance the dentists' position.

## Notes on Current Topics.

### Euthanasia.

The doctrine of Euthanasia, with which some cultivated sections of society have dallied of late, is evidently not viewed with favour in our Courts of Justice. Mr. Justice Hawkins, in charging the jury at the trial of Paine for the murder of Miss Maclean, on the 24th ultimo, said—"It is equally criminal by the law of this country to accelerate by one hour the death of a person as to cause it;" and when passing sentence he observed—"I can conceive nothing more atrocious than the exclamation you made on the last morning on which that poor creature saw the light of day; to her you said it was a sin to preserve such a life." Perhaps the last observation on the part of the Judge was a little over-strained. Paine was shown to have been a most cruel and degraded criminal, and it is therefore allowable to put the worst construction on everything that he said; but exclamations not very dissimilar to that which called forth the indignant condemnation of the Judge are not rarely used in the hearing of medical men by persons who have no evil designs, but who, being simply coarse and uneducated, are tainted by a spurious philosophy, or bewildered by the inscrutable mystery of human suffering. Nay, intense sympathy and affection, baffled by poverty in their strivings to alleviate the pangs of sickness, sometimes find utterance in prayers that the struggle may be ended, and the balm of death sent quickly.

To the medical profession Euthanasia has no meaning beyond the obligation which rests on them to contend with pain to the last, and to pluck bitterness from the death-bed as far as that can be done without curtailing for one second that life which it is their opportunity and which it is their mission from first to last to tend and foster.

## A Chemist's Blunder.

At Newcastle-on-Tyne an inquest was recently held on the body of a boy who had died from the consequences of a cut in the knee, the immediate cause being "lock-jaw." In the evidence it came out that a chemist undertook the surgical treatment of the case, and proceeded to stitch up the wound, continuing his attentions for some days subsequent to the accident. The boy did not improve, and ultimately died. The coroner, in accordance with a desire expressed by the jury, severely censured the chemist for his presumption in dealing with a case that should have been seen to by a duly qualified practitioner; and the justice of the reprimand was apparent from the assertion of Dr. Redmond, who was called to the case just before death, that the boy's chances of recovery would have been materially advanced by his removal to the infirmary. This instance would probably not have come to light had not the ill consequences of the unskilled treatment to which the patient was subjected been followed so quickly by the fatal issue. A great number of minor surgical operations are, without a doubt, daily performed by chemists; and although it may be, and indeed very probably is true, that a considerable minority of them are effected with some degree of skill, yet the very evident danger to which the public must be submitted by the prevalence of the practice should be a proof that it is against its interest to allow *any* chemist to operate as a surgeon in the absence of his fitness to do so as certified by a surgical qualification.

## Oleomargarine.

The manufacture of "Oleomargarine," or imitation butter, is carried on to a very considerable extent in the United States, and recently some controversy has arisen concerning the suitability or otherwise of the material as an article of food. In consequence, too, of representations made in this country, our Board of Trade has caused inquiries to be instituted as to the amount of oleomargarine exported to England from America. The result has been to show that comparatively little of the compound finds its way here, the bulk of it going to the Continent. There is little doubt, however, that no inconsiderable amount of the so-called butter brought to our ports from Holland and other places is in reality oleomargarine put in tubs to look like the natural product, and hence, being sold under a deceitful guise, it becomes really an adulteration. In the case of the open sale of oleomargarine, under its legitimate name, there can be no objection made to such a sale; but when the vendor intentionally deceives his customers, he should be dealt with under the act which enacts his punishment. The evil effects of the artificial compound have been shown to be nil, and if it can be sold at a rate to bring it within the reach of the poorer classes, there should be no bar placed upon its consumption. Only, we repeat, the strongest discouragement should be given to any attempt to palm off as *butter* the manufactured product of fats. But that this is largely done at present, we venture to believe.

## Aid to the Injured.

The Blackheath Central Committee of the St. John Ambulance Association has just issued its report for the year ending 31st Dec., 1879. From it we learn that instruction in bandaging and elementary minor surgery has been given by lectures and demonstrations to 463 women and 285 men during the year. Of these 265 women and 141 men obtained certificates of proficiency in the subject of instruction, after having undergone examination therein by the teachers. The lectures are delivered at different places, and in every one the attendance has been extremely satisfactory. The balance-sheet shows a sum in hand of £11 14s. 2d., and this after payment of all expenses, and also of £60 rent to the central executive committee towards defraying the expenses of instructing the Metropolitan Police and poor districts. It may be that this flourishing state of affairs is due to the energetic way in which the hon. secretary, Mr. C. D. Davies, has performed his duties; but the example should prove a salutary one, and other districts might emulate the success achieved by the Association in the Blackheath centre. That incalculable good results from these classes is manifest; already numerous cases of prompt assistance rendered, when but for it death must have ensued, being recorded. We cordially wish success to the Association's endeavours.

## Patent Medicines in Switzerland.

The *Chemist and Druggist* considers that patent medicines are entering on a bad time on the Continent, if not in England. In Germany, where their sale is prohibited by law, the stupidest remedial swindles are popular. In Russia a paternal Government watches at the gates of entry for them, and prohibits all but a favoured few. All sorts of precautions are taken in France against dangers resulting from unofficial combinations, and yet Paris is the centre of a trade in them of enormous proportions, in the benefit of which Spain, Italy, Belgium, Holland, Turkey, and Austria chiefly share. A vigorous attempt is now being made to keep them out of Switzerland. A Bill has been introduced into the Swiss Federal Assembly which prohibits the sale or advertisement of secret or special medicines which contain poisonous or very active substances, or of which the price is out of proportion to the value of the ingredients, or if the advertisement shall be injurious to public morality, or if the medicines are recommended for acute diseases. A commission of competent men is to be appointed to decide what are the specialties which fall under either of the named sections. Penalties of 20 francs to 200 francs are imposed, and publishers of journals are to be held responsible for advertisements of interdicted remedies in their pages.

## Breach of Harmony at a Special Hospital.

The following excerpt is from the *Newcastle Daily Journal*:—

"Throat and Ear Hospital, Newcastle-on-Tyne. Extract of Minute read by Dr. Wicks, at a Committee Meeting, held in the Hospital in December, 1879. Henry Downie, Esq., in the chair. 'Mr. Chairman and Gentlemen,—This meeting was called to consider certain rules for the working of the Institution. Since the last meeting was held, however, certain circumstances have come to light, which render it absolutely impossible for Dr. Torrance and myself to be any longer associated in any way whatever with the other medical officer, Dr. Ellis. . . . Under all these circumstances, much as we regret severing our connection with an Institution which has done so much good, it is absolutely impossible to work any longer with him; either he, or we, must retire.' Referring to the above extract of minute, as Dr. Ellis refused to retire, we, the undersigned, have ceased to have any connection with the Throat and Ear Hospital, 1 Clayton Street East, Newcastle-on-Tyne. (Signed)

"WM. CAIRNS WICKS.
"February 4th, 1880." "ROBERT TORRANCE.

In the absence of any particulars further than those contained in the above notice which has been forwarded to us, we are unable to speak definitely on the matter it refers to. *A priori*, however, the fact of medical officers of a public institution feeling it necessary to resign all official connection therewith, indicates the probability of some serious obstacle to prevent their harmonious association with the other member of the staff. Possibly we may be favoured with Dr. Ellis's explanation.

## Cremation among the Indians.

AMONG certain sections in India cremation has been practised from time immemorial, but their proceeding has absolutely nothing in common with that now sought to be introduced into this country, if we may judge by an article which has appeared in an American contemporary. The writer recently witnessed the funeral ceremony over the wife of an Indian, which he thus describes:—The body having been placed on a horse, the procession started; no music was heard save the buzzing of millions of flies round the corpse. On arriving at Anthony House Camp the body was placed on an immense mass of wood; it was then set on fire, and the Indians, with the help of pointed sticks, stirred up the funeral pile; then surrounding it they held the body in the middle of the flames, uttering now and then a savage cry as if to increase the fury of the flames. The custom then follows to gather up the ashes in a sack and bring them back to their homes, to make of it, with a mixture of tar, a sort of paint. This tarry matter is used specially for the ladies' toilet, and it is treasured as a great luxury.

## Heredity.

THE *Journal of Science* remarks that for several generations the Darwin family has been distinguished for an intelligence far above the average, which, in two cases at least, has risen to the rank of genius. Almost all its members have possessed scientific tastes, and have followed the learned professions generally with success. We read that Robert Darwin, the father of Erasmus, was a man given to scientific pursuits; he left two sons, Robert Waring, a poet and botanist, and Erasmus. Of the children of the latter, five reached maturity:—Charles, who had already become distinguished as an anatomist, when he died from the effect of a dissecting-room wound; Erasmus, a statistician and genealogist; Robert Waring, a skilled and eminent physician, father of *the* Darwin of to-day; Francis, a naturalist of merit; and, Violetta, who became the mother of Mr. Galton, the author of the well-known treatise on the "Heredity of Genius." A son of Francis, Captain Darwin, in his "Gamekeeper's Manual," shows keen observation and knowledge of the habits of various animals. The two sons of Dr. Charles Darwin, George and Francis, have not merely taken part in their father's researches, but have entered into independent scientific researches.

## London Water Supply.

DR. FRANKLAND reports, as the results of his examination of the water supplied to London by the several water companies during the month of January, that, taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the Metropolitan Water Companies and by the Tottenham Local Board of Health was:—Kent 1·6, Colne Valley 1·6, Tottenham 1·7, West Middlesex 2·2, East London 3·4, New River 4·3, Chelsea 4·7, Grand Junction 4·9, Southwark 5·2, Lambeth 5·9.

The Thames water supplied by the Chelsea, Southwark, Grand Junction, and Lambeth Companies was greatly inferior to that sent out by the same companies in December. The West Middlesex Company, however, whilst taking water from the same source, reduced the proportion of organic impurity to less than one-half before distribution. All the Thames water was efficiently filtered, except that supplied by the Grand Junction Company, which was slightly turbid, and contained moving organisms.

The Lea water distributed by the East London Company was of superior quality, but that sent out by the New River Company was only slightly better than Thames water. It was efficiently filtered by both companies.

The deep-well water supplied by the Kent and Colne Valley Companies, and by the Tottenham Local Board of Health was of its usual excellent quality for dietetic purposes, and that sent out by the Colne Valley Company was suitable for all domestic purposes, having been softened before delivery.

Seen through a stratum two feet deep, the waters presented the following appearances:—Kent, Colne Valley, and Tottenham clear and colourless; West Middlesex clear and nearly colourless; Chelsea and East London clear and pale yellow; Southwark, Lambeth, and New River clear and yellow; Grand Junction slightly turbid and yellow.

Lieut.-Col. Bolton, the Government water examiner, reports, in addition to the foregoing, that the water at all the intakes was generally in an indifferent condition during the month, in spite of efficient filtration. The companies, however, are generally moving in the matter of giving a constant supply under the provisions of the Water Act.

## The Vacant Commissionership of Irish Poor Law.

THE seat in the Irish Local Government Board vacated by the death of Mr. R. M. Bellew has not yet been filled, and we rejoice to believe that the chance of its being made a sinecure for the accommodation of Mr. George Morris, M.P., is less than it was.

In the House of Commons last week, in answer to Mr. Gray, Mr. J. Lowther said the question of permanently filling up the vacancy upon the Local Government Board in Ireland had not been finally decided upon, but arrangements were in course of being carried out with the object of temporarily strengthening the Board, and he was in hopes that the services of a gentleman possessing a wide experience of the administration of the Poor Law might be secured for that purpose.

We don't like the expedient of "temporarily strengthening" the Board, especially as there can be no reason but a political one for delaying the permanent appointment of a competent person to the vacant office. We derive consolation however—and some hope that the Irish medical charities system may escape Mr. George Morris—from the Chief Secretary's statement that he is in hope of appointing "a gentleman possessing wide experience of the administration of the Poor Law." Mr. George Morris certainly does not answer this description, and Mr. O'Brien, one of the other eligible candidates, certainly does, and, as it is rumoured that there is £2,000 a year waiting for the honourable gentleman in another department, we encourage the hope that he will accept the latter office.

## The Netley Competitives.

Sir George Balfour has given notice of his intention to move for returns from the Army, Naval, and Indian Medical Departments, showing—

1. Number of candidates examined annually from 1870 to 1879.
2. Total marks attainable by each candidate.
3. Number of candidates passed.
4. Highest and lowest marks obtained, taken not individually, but in the aggregate.

## Cheap Dietaries.

On Saturday last the medical and lay press were invited to a private view of a large restaurant in London, which was to be opened to the public during the present week, on purely vegetarian principles. The success of the Manchester establishment is said to be so great that it is intended to open other houses in all large centres gradually. For some time past the thing has been tried in the metropolis on a very limited scale at 429 Oxford Street, which, when we visited it out of curiosity a short time since, was so well patronised that there were no empty seats available. Whether the small minority of vegetarians which is supposed to exist in every community will be found sufficient to support large establishments like that which was opened this week in the Farringdon Road time only will show. Having devoted several articles lately to the food question, founded on the results of practical experience, we are far from thinking that a dietary of vegetable soups, vegetable savouries, milk puddings, and fruit, should be limited to professed vegetarians. On the contrary, nothing will be found more wholesome more nutritious, or more conducive to sound health than a change to this from a meat diet once or twice a week, as proved by the researches of Carpenter, Pavy, Bland, Radcliffe, Playfair, Parkes, Letheby, and others. Whether the enterprise succeeds as a monetary venture we are not concerned; for the public it is a step in the right direction, and on economical grounds as well as for health, it were well for them to know that a little less from the butcher and a little more from the greengrocer would be better for them in both respects. For the economist we may add that each dish is served at threepence, except the *pièces de resistance*, "the savouries," which are fourpence, and that the coffee (alcohol not being allowed on the premises), made from Branson's extract, at twopence per cup, is as good as one need wish to have.

## The Registration (Ireland) Amendment Bill.

This Bill, which was prepared by the Council of the Irish Medical Association, and introduced two years since by the Earl of Donoughmore in the House of Lords, has been entrusted by the Association to Mr. Meldon, M.P., who has introduced it into the Commons, and got it through its first reading. It stands for second reading on next Tuesday, the 9th of March. It is a technical measure, of interest only to the registrars of births, deaths, and marriages in Ireland, whose work it greatly facilitates, while it will, if passed, greatly improve and simplify the public working of the system, and we therefore transfer its details to the Irish Supplement of this Journal. We understand that its principles have met with the approval of the department responsible for registration, and we may, therefore, hope that it will become law.

## The Royal Medical Benevolent College Election.

In another column there appears a communication from the Hon. Sec. of the Committee of Governors of the Medical Benevolent College, charged with the duty of obtaining an improvement in the mode of election. The Council of the College, loyally accepting the expression of opinion of the majority of governors, at once set to work to devise a scheme which will, we believe, be generally acceptable. A committee of selection has also been appointed, half of whom will go out of office in rotation. The Committee of Governors are to be congratulated on the successful termination of a long war waged against the abuses of the voting system in the Medical Benevolent College. The recognition of the evils of voting by our profession cannot fail to exert a widely extended influence, and the conclusion arrived at will, we trust, be the means of securing the benefits of the College to the most deserving amongst the candidates.

## Vaccination.

On the second reading of Dr. Cameron's Animal Vaccination Bill, which is fixed for the 10th of March, Mr. P. A. Taylor is to move "That, in the present unsettled condition of medical opinion in regard to the safety of using ordinary humanised lymph, as also of the safety, effectiveness, and practicability of the use of animal vaccine, it is, in the opinion of this House, inexpedient and unjust to enforce vaccination under penalties upon those who regard it as undesirable or dangerous." Would Mr. Taylor be good enough to inform us what he means by "the present unsettled condition of medical opinion?" Is there even an insignificant fraction of medical opinion or half-a-dozen medical men whose opinions are worthy of notice "unsettled" on the subject of vaccination? No doubt a very few obscure practitioners, who must secure notoriety, no matter how it is got, have refurbished old fallacies, and published them as their own ideas; but there is nothing on which medical opinion is so firmly fixed as it is in favour of vaccination. Dr. Cameron, M.P., also has given notice that on going into Committee of Supply on the Civil Service estimates, he will "call attention to the result of the system of public vaccination pursued in this country, and will move a resolution on the subject."

H.R.H. THE PRINCE OF WALES will take the chair at Willis's Rooms, on Saturday week, at the Festival Dinner in aid of the funds of the Westminster Hospital.

H.R.H. PRINCE LEOPOLD has consented to preside at the annual Festival Dinner on Thursday week, in aid of the funds of University College Hospital.

SIR JAMES PAGET, BART., F.R.S., will preside at the annual Festival in aid of the funds of the Hospital for Sick Children, Great Ormond Street, Bloomsbury, on the 8th prox.

AT a meeting of the council of the St. Andrew's Graduates Association, held a few days since, it was unanimously resolved that it was outside the duty of the Association to take official part in the coming election of Member of Parliament for the conjoined Universities of Edinburgh and St. Andrews.

WE understand that a committee of members of the House of Commons representing all political parties has been formed for the purpose of co-operating with the medical and other committees in Dublin in furthering a public subscription to the family of the late Dr. O'Leary, M.P.

A WELL-KNOWN provincial member of the profession passed away from us last week in the person of Dr. Copeman of Norwich. Deceased had been for many years physician to the Norfolk and Norwich Hospital, and at the annual meeting of the British Medical Association in 1874, held at Norwich, he was made Vice-President and presided over the meeting. He was the author of several contributions to medical literature.

IN the principal large towns of the United Kingdom last week, the rates of mortality per 1,000 were—Brighton 12, Portsmouth 18, Leicester 20, Oldham 20, Wolverhampton 20, Newcastle-upon-Tyne 21, Sunderland 21, Leeds 21, Bradford 21, Bradford 21, Sheffield 22, Birmingham 22, Edinburgh 22, Salford 24, Liverpool 24, Bristol 25, Manchester 26, Glasgow 26, Hull 28, London 29, Nottingham 31, Norwich 35, and the highest rate was 38 in Plymouth and Dublin.

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns, were—in Calcutta 27, Bombay 35, Madras 46; Paris 38; Geneva 41; Amsterdam 38, Rotterdam 35, The Hague 26; Copenhagen 33; Stockholm 27; Christiania 16; St. Petersburgh 48; Berlin 25, Hamburg 25, Dresden 22, Breslau 30, Munich 39; Vienna 31, Buda-Pesth 34; Rome 53, Turin 43, Venice 37; Alexandria 41; and New York 26 per 1,000 of the population. Small-pox caused 70, and typhoid fever 73 more deaths in Paris.

THE death-rate last week from the seven principal zymotic diseases ranged from 0·8 and 1·4 in Portsmouth and Oldham, to 5·8 in Dublin, 5·9 in Hull, and 9·7 in Plymouth. Measles showed the largest proportional fatality in Plymouth, Nottingham, and Hull; scarlet fever in Sunderland and Bradford; and whooping cough in London, Salford, Hull, and Newcastle-upon-Tyne. Eleven deaths (including 7 in the workhouse) were referred to enteric fever in Sheffield, against 4 and 10 in the two previous weeks. Small pox caused 13 more deaths in London, and 6 in Dublin.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

EPIDEMIC OF MEASLES AT COATBRIDGE.—A rather alarming epidemic of measles prevails at present in the parish of Old Monkland, and at the largest school, where there are upon the roll 960 children, there are about 200 absentees from this cause alone. The epidemic is of a mild type, and only one or two deaths have occurred.

GLASGOW.—POISONED WITH CONFECTIONS.—A child, æt. 5 years, named Murdoch McLeod, exhibited symptoms of poisoning from eating confections last week. Drs. Walker, Miller, and Buchanan gave it as their opinion that he had been poisoned by the colouring matter of the confections.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—The annual dinner of the Royal Medical Society was held on the 24th ult. in the Waterloo Hotel, Edinburgh. Dr. Greves, Senior President of the Society, occupied the chair, and Dr. Caverhill acted as croupier. Among those present were, the President of the Royal College of Physicians (Dr. Haldane), and the President of the Royal College of Surgeons (Mr. Imlach), Professor Annandale, Dr. Angus Macdonald, Surgeon-Major Robertson, Dr. Keiller, Professor Turner, Professor Gairdner, Dr. Clouston, Dr. Heron Watson, &c. Surgeon-Major Robertson, in responding for the Army, said that he had often been asked for advice by medical students as to whether they should go into the army or into private practice. Well, that depended entirely on their own individual inclinations. His own private opinion was that the army, as compared with private practice, and taking it all round, had for the majority of medical students more advantages and few disadvantages. He hoped the army would always have a large infusion of the men of Edinburgh, because he believed they furnished the best medical officers the army could have. The chairman, in giving the toast of the "Royal Medical Society," said the Society was generally regarded as the junior medical society in the city, inasmuch as it was almost exclusively supported by the junior members of the profession. But when they remembered that this was the first scientific society inaugurated in the city of Edinburgh—a city which had ever been famous as a seat of scientific learning and culture; that it was founded in 1737—47 years before the Royal Society was instituted—he thought they would agree with him that in that sense they should rather consider it the senior society. They held a position of which they had every reason to be proud, more especially when they remembered that long list of illustrations names who had gone forth from this Society to become foremost in the ranks of science; men like Cullen, Black, Gregory, Bright, Simpson, Syme, and a host of others. At the present time he was happy to say the Society was in a most flourishing condition. The President also stated that in virtue of an Act of Parliament passed in the early years of the present reign, it has been found that the premises of the Royal Medical Society were not liable to be rated for municipal purposes; also that fines for non-attendance at the weekly Friday meeting of the Society had been abolished. The result of this relaxation had been that last year they had the maximum number of new members—viz. 55—who had ever joined the Society in one year. They were all deeply indebted to the Professors of the University for the support they had given to the Society during the year.—Professor Fraser, in responding to the toast of the "Edinburgh and Scotch Universities," remarked that the most remarkable feature of their own University was the rapid increase of its students, the number at present being 2,800, a figure to which few universities in Europe had attained. Professor Gairdner, of Glasgow, also replied, and stated that the University of Glasgow had now over 2,000 students. He further indulged in a verbose threnody on the subject of the contemplated medical reform, and tried to show, in a manner not distinguished by logical precision, how, if conjoint boards were established whose pass would qualify, it would develope, not liberal culture, but "cram," and especially prove baleful to studies in the primary sciences, which was one of the characteristics in the Unviersity of Edinburgh. He animadverted on the teaching of the so-called initiatory sciences in London, and how the new *régime* would prove hurtful to the "liberal science" (!) of botany. He asked all connected with the University of Edinburgh to come to the front and assist in resisting this conjoint board system with which they were threatened. Other toasts followed, and the sentiment *Floreat res medica* (which we venture to assert three-fourths of the members of the liberal profession of medicine in Scotland are unable to construe, except in *this* manner) was "dluy honoured" previous to the termination of the proceedings.

**Dr. Mathew Charteris.**—Dr. Charteris, of Glasgow, is, we understand, a candidate for the Chair of *Materia Medica* at the University of that city, which becomes vacant through the resignation of Professor Cowan. Dr. Charteris has considerable experience as a lecturer, and is understood to be very popular with the students, while he is well known to be a judicious physician. He possesses strong claims to the consideration of the Crown, in whom the appointment is vested. Several other candidates, all local as yet, are spoken of, but their intentions have not been publicly announced.

**Registrar-General's Report.**—According to the weekly return of births, deaths, and marriages in the eight principal towns of Scotland, the death-rate for the week ending with Saturday the 21st February, 1880, was 25·5 per 1,000 of estimated population. This rate is 1·3 above that for the corresponding week of last year, and 2·3 above that for the previous week of the current year. The lowest mortality was recorded in Greenock—viz., 20·3 per 1,000, and the highest in Perth—viz., 39.0 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·7 per 1,000, being 0·6 above that for the previous week. A slight increase occurred in the number of deaths from measles and whooping-cough. In Leith 4 deaths resulted from measles, and 3 from scarlet fever. Three of the deaths recorded in Dundee were of persons who lost their lives by the Tay Bridge accident. The number of deaths from inflammatory affections of the respiratory organs was 169, or 20 more than the number recorded during last week.

**Glasgow University Court.—Resignation of Professor Cowan.**—At a meeting of this Court held on the 23rd ult., present all the members except the Lord Rector and Dr. James A. Campbell, there was presented in the usual form a petition by Professor Cowan, praying the Court to report to her Majesty in Council in favour of his application to be allowed to retire from the chair of Materia Medica in consequence of the state of his health.

**Death of Dr. Fiddes, Aberdeen.**—Dr. David Fiddes, one of the oldest and best known medical practitioners in Aberdeen, died on the afternoon of the 25th ult., after an illness of barely four days' duration. A native of Aberdeen, he was educated in her seminaries and at her University, and as was the custom in those days, when Scotch medical degrees were not in such high repute as now, went south, and in 1832 passed M.R.C.S. Eng., following this up eleven years later by taking the M.D. degree at Marischal College. Immediately after becoming a member of the Royal College of Surgeons he accepted an appointment as surgeon on board an East Indian, and made several voyages to the East. Dr. Fiddes afterwards settled in Aberdeen, where by degrees he built up a practice in both branches of his professional work, which was possibly one of the best in the north. At one time Surgeon to the Royal Infirmary, a post which he held for many years, he was on his retirement appointed Consulting Surgeon, an office which he held to the last.

### LECTURES ON THE DISEASES OF WOMEN. (a)

The revising editor says in his preface that "it would be almost absurd in the present growing state of gynæcology to look for identity of opinion or view in any two authors," but he goes on to say that in the tone and spirit of the work he heartily concurs. His (Dr. Matthews Duncan's) contributions to the text are enclosed within brackets, and we are disappointed to find that they are infrequent.

The class of specialists, the "lady doctors," to which the authors belong is especially the object of suspicion on the part of many medical men, which leaks out in expressions such as "balancing the uterus on the sound," accusations of cauterising the os uteri to cure any and all female ills, and similar charges, founded on fact, perhaps, which all medical men have heard some time or other. No doubt this is in great measure due to the liking women—especially those of the middle and upper classes—appear to have for being told that their maladies are dependent on uterine derangement. One can easily understand that it is satisfactory to be told that languor and pain in the side are the result of anything so simple, and therefore curable, as a "displacement"—a twist of the sound sets it right, and the patient must "rest." And there is a dash of mystery about the lady who has "an internal complaint," and who is usually a typical professional invalid—*ubi stimulus ibi fluxus*—and this female weakness for "internal complaints" has found encouragement from those men who practise medicine for profit only. Probably this is the reason why in times past this most important subject, gynæcology, has fallen into disrepute; but another factor has been the ignorance about this class of diseases which did exist in the profession, and which led to the antipathy which the unlearned feel for the learned. Their feelings of mistrust are now wearing out, and would never have been produced by such

---

"Lectures on the Diseases of Women." By Charles West, M.D. Fourth edition. With numerous additions by J. Matthews Duncan, M.D., F.R.S.E., Obstetric Physician to St. Bartholomew's Hospital. London: J. and A. Churchill. 1879.

a method of dealing with women's maladies as we find in the present work, the writer, though an obstetric physician, being a *physician* emphatically. For instance, in the treatment of uterine versions and flexions, Dr. West says—"To the best of my power I take care of the general symptoms, and leave the misplacement to take care of itself." In the treatment of uterine fibrous tumours the author speaks of the use of the German mineral waters to express his disbelief in their power of reducing the morbid growth; would such treatment ever be expected to benefit such tumours in other parts of the body?

Dr. West then handles a certain operation which has lately been "forced into notoriety—spaying women in cases of obstinate dysmenorrhœa—and which, in spite of an admitted mortality of one in five of those who submitted to it, is spoken of with intense satisfaction by its advocates as a great therapeutical discovery of no very narrow application."

An old friend appears at page 407—"spermaceti draughts"—which some of the younger members of the profession probably never heard of, though living medical men can remember their use for a month after parturition as orthodox practice, and Shakespeare himself recommends spermaceti as a sovereign remedy for an inward bruise.

In alluding to cysts of the broad ligament—parovarian cysts—Dr. Matthews Duncan says that, as compared with true ovarian cysts, they are uncommon, but that they are generally unilocular, and the fluid they contain is like limpid water, having no albumen; whereas the ovarian cystoma is probably always multilocular, and its contents are frequently colloid, and almost constantly albuminous. The parovarian growths are more amenable to simple methods of treatment than those of the ovary itself.

Solid tumours of this organ are, he says, comparatively rare, as one would expect in a structure of such limited activity, and growths which are described as arising from the ovaries may be supposed in many cases to have taken origin from other tissues in the neighbourhood.

The present—the fourth edition of the oldest standard work on diseases of women (of any note)—has been carefully revised and brought up to the most recent gynæcological knowledge, and the assistance of an editor from a fresh school of medicine has had a good effect on the book.

# Correspondence.

## A SIMPLE METHOD OF EVACUATING SMALL CALCULI.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Amongst your Notes on Current Topics in the issue of February 25th, you draw attention to "A Simple Method of Evacuating Small Calculi," and give credit to Dr. Mercier for having recently demonstrated before the Société de Médecine of Paris an easy and practical means of getting rid of small calculi. It consists, you describe, in making the patient lie on his belly, then the calculi fall by their own weight into the anterior part of the bladder. The patient is then allowed to rise slowly on to all fours. He micturates in this position, and the calculi, which have not yet had time to return into the cul-de-sac behind the prostate, are carried away in the stream of urine.

This practice I have adopted for years with success; and you may find it described in my work "On the Practice of Surgery," published in 1873, under the heading of "Treatment of Hypertrophy of the Prostate," as follows:—"Patients with this affection should, as a matter of habit, once a day pass urine on their hands and knees; in this way the bladder has more power to evacuate its contents, and the mucus and *other more solid contents* that otherwise would lie behind the prostate are got rid of with greater certainty" (p. 73, vol. ii., 2nd edition). I believe this suggestion to be a good one, and am thus induced to send you the correction contained in this letter as to priority.

I am, yours, &c.,

THOMAS BRYANT.

53 Upper Brook Street, Grosvenor Square, W.
February 26, 1880.

---

## THE IRISH LECTURE CERTIFICATE SYSTEM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to the article in your issue of the 14th inst. on "The Irish Lecture Certificate System," I think there are some assertions which should not be allowed to pass without comment. You state that—"Finding that neither a personal presence at lectures or hospital, nor medical study of any sort, was essential to the obtaining of certificates of 'diligent' attendance, a large number of young men have been encouraged to enter the medical profession without any real medical study whatever. These *soi-disant* students are engaged for the entire working day, and often for the evening also, behind counters in shops, banks, and offices, and their system has been to enter their names for lectures and hospital at the beginning of each session, to occupy the three years of their supposed study in putting together the money for the subsequent purchase of the certificates, and, at the end, to resign their employment, buy up the documents, and devote themselves ardently to six months' grinding, and to the passing of their examination." Now, Sir, you must be unaware of the amount of professional knowledge necessary to obtain a diploma from any of the licensing bodies of Great Britain or Ireland, to state that men, after six months' grinding merely, could pass the necessary examinations. You also state that "it is a well-known practice for needy students to undertake service behind an apothecary's counter, and to continue in that employment steadily and regularly engaged in dispensing and attending to the shop business until within a few months of the time of their examination, at which period, having saved up by their service behind the counter a sum sufficient to pay for their certificates of 'diligent' attendance at hospitals and lectures, and for the services of an experienced 'grinder,' they leave the service of the apothecary, submit themselves to a hasty 'cramming,' and are in due time impressed with the stamp of medical competency by a licensing corporation." These men are all allowed a certain number of hours daily to attend hospital and lectures, as you will find by referring to the advertising columns of any of the medical papers, and I could name several of these men who now hold commissions in the Indian Medical Srvice, and other responsible posts, which they could never have obtained if they were so totally ignorant of their profession as your article would lead people to believe.

I can state from my own knowledge that the students of what Dr. Haughton describes as a "certain medical school in Dublin" have been more successful at the examinations of the College of Surgeons during the past year than those of any other school in Dublin, a remarkably small percentage having been rejected; in fact, at one recent examination, not a single man failed; and at an examination held at the commencement of last year, for the "first half" of the College of Surgeons, England, the only successful Irish candidate was a student from this school, and, strange to say, an assistant in an apothecary's establishment. It is a well-known fact that the average Trinity medical student, who is compelled to strictly attend lectures, cannot compete in knowledge of anatomy with the student of other Dublin schools, which do not enforce such a strict attendance at lectures. If examinations are not a test of a student's proficiency, what is? Surely not the fact of his having attended a certain number of lectures, from which—it rests with himself—he may or may not have derived benefit. From my own experience as a student, I can state that the time I occupied in attending *some* lectures might have been far more profitably spent in either dissecting or "grinding." By inserting this letter in your influential columns you will much oblige

Your obedient servant,

AN EX-STUDENT.

Dublin, 27th January, 1880.

[The remarks of our correspondent are arguments for requiring no curriculum at all, but they afford no reason for tolerating a sham curriculum. He seems to admit fully the charges we have made against the Irish certificate system, but he argues that very good practitioners can be made without the required course of study.

We know of cases in which students have, with six months' grinding, supplemented by a very little previous reading, obtained diplomas. We also know that the "hours for attendance of lectures" by students who are engaged in dispensing are often imaginary, and are sometimes not employed in any such attendance. It is not *ad rem* to argue that individuals have been successful in spite of their never having fulfilled their curriculum of study. Even if true, this would not prove that all students should be allowed the opportunity of doing so.—Ed. M. P. & C.]

◆

## PRESENTATION TO MR. LAMBERT H. ORMSBY, L.R.C.S.I.

On Saturday week an address was presented to Mr. Lambert H. Ormsby, L.R.C.S.I., surgeon to the Meath Hospital, by the past and present students of that hospital. The proceedings took place in the theatre of the hospital. The chair was taken by Mr. Porter, senior surgeon to the hospital and surgeon to the Queen.

The following members of the medical staff were present—Dr. J. W. Moore, Mr. Smyly, Mr. Rawdon Macnamara, Mr. Hepburn. There were also present—Messrs. George F. Fisher, David Smith, R. Lyle, Mr. Crozier (house surgeon), — Finigan, A. B. M'Kee, J. H. Parkinson, L.R.C.S.I.

The Chairman remarked that he cordially approved of the course adopted by the students, which reflected the highest credit, not only upon Mr. Ormsby, but also upon them themselves.

Mr. Parkinson said he had been desired on behalf of the committee to present to Mr. Ormsby a testimonial of their respect and esteem. When it became known that he was about to resign the honorary secretaryship of the medical board, a general feeling was manifested amongst the students to show some token of their approbation of the way in which he had discharged the duties of that office, and also of his efforts on their behalf as a clinical teacher. He was speaking the sentiments of the entire body of students when he said Mr. Ormsby had always done his best for them. In conclusion he would, on behalf of all, wish Mr. Ormsby long life, every happiness, and continued professional success. Those of them who would soon be leaving would, in bidding him farewell, testify their approbation of the "old Meath" by sending from time to time others to that place, where, they felt themselves, they had acquired what was to be their capital in the life they would be entering upon (applause).

The address, beautifully designed and illuminated, was then presented amidst applause to Mr. Ormsby, and was accompanied by the presentation of a massive gold ring.

Mr. Ormsby then briefly replied, thanking them for their kind and complimentary expressions. The address had proved that his exertions for the past eight years had met with their approval (applause). He gratefully accepted it, and desired to state that he fully appreciated their testimony to the manner in which he had discharged his duty. He hoped the relations now existing between them would grow and deepen to their mutual good.

The proceedings then terminated.

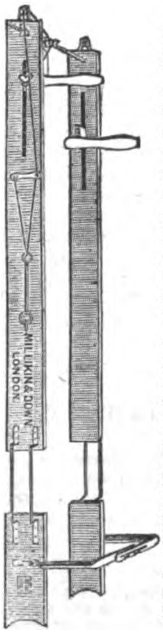
◆

## THE SCHOOL OF DR. STEVENS'S HOSPITAL, DUBLIN.

We understand that our anticipation of the regrettable effect upon the School of the recent election at Dr. Stevens's Hospital, Dublin, has been verified, and that Dr. Robert MacDonnell has resigned his position as Lecturer on Anatomy in the School. It is said that the resignations of other lecturers in the institution are to follow immediately, and, if so, we may assume that at the conclusion of the present session the School will close its doors. The result, though we greatly regret it, does not surprise us.

# Novelties.

## A NEW SPLINT FOR HIP INJURIES.



Mr. Bryant, Surgeon to Guy's Hospital, has perfected an improved form of splint for use in diseases and injuries of the hip and femur. The special features of the instrument are an arrangement by means of which the parallelism of the extremities is maintained, a point on which Mr. Bryant lays special stress, and which in the treatment of the cases for which his double splint is devised, he assumes is too little considered. By an ingenious construction, well-regulated and persistent extension of the limb is kept up, and thorough immobilisation secured. The improvement appears to be a very valuable one, and by aid of it there seems a probability of reducing the great number of disfigurements by shortening consequent on operations on the hip. The new splint is applicable to cases of fracture, whether in the neck of the thigh bone or in the shaft; and one great advantage connected with its use is that it permits easy and safe change of position on the part of the patient, no fear of disturbance of the injured parts being entertained when it is once firmly adjusted. The general form and construction of the apparatus will be clear from the appended engraving.

◆

## EMS NATURAL MINERAL WATER.

This water is from the Victoria Rock Spring, and has been long celebrated. It may be classed among the alkaline mineral waters, and contains 200 parts of bicarbonate of soda in every 100,000, together with some small quantities of chloride of sodium, bicarbonate of lime, and bicarbonate of magnesia. It is a pleasant water for the table, and is useful for its slight medicinal action in constipation or dyspepsia. The Company has recently appointed an agent in this country for its waters and pastilles, both of which can now be obtained, put up in the ordinary form of all mineral water dealers, or of the agent, Mr. Massingham, 16 Union Court, London, E.C.

**King and Queen's College of Physicians.**—At the February examinations the following obtained the licences in Medicine and Midwifery of the College:—

Medicine.

Allman, Robert
Fisher, George Edward
Hayes, John Joseph
Lyle, Robert Charles
M'Coy, Michael Joseph
M'Dowell, Benjamin George
O'Donovan, Jeremiah
Marshall, Mary Adamson
Miller, John Alex.
Palmer, Walter Stephen
Taylor, Thomas Cathcart

Midwifery.

Allman, Robert
Alvares, Nicolas Santana
Fisher, George E.
Hayes, John Joseph
M'Coy, Michael J.
Marshall, Mary Adamson
O'Donovan, Jeremiah
Sharpe, Alexander
Taylor, Thomas Cathcart
Williams, J. Almericus de Courcy

**The Seamen's Hospital, Greenwich.**—The annual court of this hospital was held last week in London under the presidency of the First Lord of the Admiralty. In an appeal which has been issued for increased support to the institution it was stated that since its foundation in 1821 upwards of 200,000 sick seamen had been relieved, of whom 30,000 were foreign. Unfortunately the hospital does not receive the amount of support necessary to maintain its efficiency, and an effort is now being made to increase the annual subscriptions from £3,000 to £5,000. Subscriptions to the amount of £500 were announced in the room.

**Samaritan Free Hospital for Women.**—The annual festival of this institution was held on Thursday last, under the presidency of H.R.H. the Duke of Connaught. In proposing "Prosperity to the Samaritan Free Hospital for Women and Children," his Royal Highness said that many of those present would no doubt have heard the story of this hospital, which was one full of interest, and he might say of satisfaction, to all those who had the welfare of their fellow-creatures at heart. It seemed almost incredible that some fifty years ago there did not exist in this metropolis a single hospital, nor even a single ward, specially devoted to the diseases of women. It was about thirty-eight years ago that a small back-room was taken in a densely-populated district of Marylebone, at 5s. a-week, to enable poor suffering women to obtain medical assistance and advice. That humble beginning met with such excellent results that the good work was continued, and, with increased means, they had ultimately founded an hospital, of which this was the festival. Since its foundation some 240,000 women and children had received out-door treatment, and 6,000 had been admitted as in-patients. Those numbers would show the enormous amount of good which had already been done. The hospital was entirely dependent on voluntary contributions, and he appealed most earnestly to those present to support it, feeling sure that in so good a cause he would not appeal in vain. Subscriptions were announced in the room to the amount of £1,682 12s., his Royal Highness heading the list with a donation of £25.

◆

## NOTICES TO CORRESPONDENTS.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," 'Old Subscriber," &c. Much confusion will be spared by attention o this rule.

**Dr. C. B.**—Thanks; too obvious to need correction.

**Royal College of Surgeons of England.**—There will be two primary examinations for the diploma of Member during the month of April next, commencing on Friday, the 2nd, and Friday, the 23rd of April, respectively. Certificates of students completing their anatomical studies at the end of the present winter session must in all cases be transmitted through the post on and not later than Thursday, the 25th of March, for the examination commencing on the 2nd of April; and for the examination commencing on the 23rd of April, on and not later than Tuesday, the 13th of that month. Certificates from Scotch and Irish students completing their anatomical studies or curriculum, as the case may be, at the termination of the present winter session, will not be received until after the close of the session in Ireland or Scotland respectively. Particulars relating to these examinations and the regulations with respect to exemption from examination in medicine, and the special required certificate in vaccination, may be obtained on application to the Secretary.

**Dr. W. H. Pearse**, Plymouth.—The paper is marked for early insertion.

**Surgeon-Major Curran**, Warrington.—We hope to find space in our next for your paper on "The Pathology of Starvation."

**Uses of Oyster-shells.**—Few probably can imagine what becomes of the tons of oyster-shells which are daily carted away from the various fish-shops. On the authority of *Le Propagature* we have it that when sufficient quantities of them have been collected, they are crushed in a mill worked by horse-power, and then put under a stamper, whence they issue in the form of a coarse powder, which, when dry, is sold to the manufacturers of aerated water, who make use of it in the preparation of a portion of the carbonic acid gas required in their trade. But this is not the only economic advantage obtained from oyster-shells. In the crushing and stamping operation, the portion known as the "gall" or "bitter" is separated from the shell. This is carefully collected in troughs, and afterwards employed in the manufacture of certain cheap kinds of soap.

**Journalistic Vagaries.**—At the Clinical Society on Friday evening, Dr. Buzzard gave an amusing account of the various ways in which the title of his paper had been announced. Only one paper (*Medical Press and Circular*) had printed it correctly. According to one, the patient died from a *kick* in the duodenum; while another, more liberal, said Dr. Buzzard, boldly declared the cause of death to be a kick in the abdomen. The announcement should be "death from a *kink* in the duodenum."

**The Medical Society of the King and Queen's College of Physicians** will meet this evening, March 3rd, at 8 p.m., at the College of Physicians, when the following communications are set down for reading:—Dr. H. Kennedy, "On Fatty Heart, with exhibition of recent specimen."—Dr. Duffey, "On Iodic Purpura."

**Obstetrical Society of London.**—Wednesday, March 3, at 8 p.m., Specimens: Dissection of a Two-headed Monster, by Dr. Godson.—Pelvic Viscera, showing Congenital Communications (1) between Rectum and Vagina, ( ) between Rectum and Urethra, by Mr. Alban Doran.—Anteflexed Uterus, by Dr. Hayes. Paper: "On Axial Rotation of Ovarian Tumours, leading to their Strangulation and Gangrene: Three Cases successfully treated by Immediate Ovariotomy," by Mr. Lawson Tait.

**The** Croonian Lectures of the Royal College of Physicians of London will be delivered on March 3, 5, 10, at 5 o'clock, by Dr. Cayley, on "Some Points in the Pathology and Treatment of Typhoid Fever."

**The** Annual Metropolitan Dinner of the Irish Graduates' Association will take place at the Holborn Restaurant on St. Patrick's Day, March 17.

**A meeting** of the Pharmaceutical Society of Great Britain will be held this evening at 8 o'clock, when the following papers will be read: "The Diffusive Properties of some Preparations of Iron," by Professor Redwood; "Note on Cantharides," by Henry G. Greenish, F.C.S.; "Volumetric Determination of Alkaloids," by J. C. Thresh, F.C.S.

**An Anti-Vaccinator's Mare's Nest.**—An amusing incident occurred in the House of Commons on Monday night which aptly illustrates the method of preparation of "statistics" by our friends the anti-vaccinators. Mr. Gourley called attention to the reports of the vaccination officers of the Durham Guardians for the year 1878, in which they stated that out of 2,381 children born in the Western and St. Nicholas district, 3'5 died from the effects of vaccination, and during the first six months of last year the number of deaths in the same union, from the same cause, were 141.

In reply, Mr. G. Sclater-Booth said the reports of the vaccination officers of the Durham Guardians for 1878 and 1879 had been carefully examined. They contained no information as to the deaths from vaccination; but they contained the number of children born, and who died previously to vaccination. As he found the numbers corresponded very nearly to the numbers quoted by the hon. member, *the excessive mortality was the mortality of the children who had died before vaccination.* Loud laughter followed, in which Mr. Gourley did not join.

◆

### VACANCIES.

Carmarthen County Infirmary.—House Surgeon. Salary, £125. Applications to the Secretary, King Street, Carmarthen, before March 31.

Chatham.—Assistant House Surgeon for the St. Bartholomew's Hospital. Salary, £80, with board. Applications to the Clerk of the Trustees before April 14.

Manchester Dispensary for Sick Children, Gartside.—Assistant Visiting Medical Officer. Salary, £180, without board or residence. Immediate application to the Chairman.

Queen's University in Ireland.—Examinership in Medicine; Salary, £100. Examinership in Surgery; Salary, £100. Examinership in Midwifery; Salary, £75. Examinership in Materia Medica; Salary, £75. Examinership in Medical Jurisprudence; Salary, £75. Candidates must address the Secretary on or before March 16. (See Advt.)

Rathdown Union, Bray and Rathmichael Dispensary.—Medical Officer. Salary, £110, with fees, and £27 as Medical Officer of Health. Election, March 8.

Seamen's Hospital, Greenwich.—House Physician. Salary, £75, with board. Applications to Mr. Burdett at the Hospital, before March 8.

Woolwich Union.—Assistant Medical Officer to the Plumstead Union. Salary, £90, with board, &c. Applications to the Clerk of the Board before March 9.

York Dispensary.—Resident Medical Officer. Salary, £130. Applications to Mr. S. W. North, F.R.C.S., 84 Micklegate, York, before March 9.

◆

### APPOINTMENTS.

**Buchanan**, G., M.D., F.R.C.P.L., Consulting Physician to the London Fever Hospital.

**Callum**, D. B., M.B., House Surgeon to the Leith Hospital.

**Cobbold**, C. S. W., M.D., M.R.C.S.E., an Assistant Medical Officer at the Middlesex County Lunatic Asylum, Colney Hatch.

**Delahoyde**, Dr. O'Connell, Medical Officer for Coleraine Street Dispensary, North Dublin Union.

**Ferrier**, D., M.D., F.R.C.P., F.R.S., a Physician for Out-patients to the National Hospital for the Paralysed and Epileptic.

**George**, W. H., L.R.C.P.Ed., L.F.P.S.G., an Assistant Medical Officer to the Middlesex County Lunatic Asylum, Colney Hatch.

**Gowers**, W. R., M.D., F.R.C.P.L., a Physician for Out-patients to the National Hospital for the Paralysed and Epileptic.

**Henderson**, G. C., M.B., Physician to the London Fever Hospital.

**Horrocks**, P., M.D., an Assistant Physician to the National Hospital for the Paralysed and Epileptic.

◆

## Births.

**Clay.**—Feb. 26, at Plymouth, the wife of R. H. Clay, M.D., of a daughter.

**Mapother.**—Feb. 21, at 6 Merrion Square North, Dublin, the wife of E. D. Mapother, President Royal College of Surgeons, Ireland, of a daughter.

## Marriages.

**Hall—Wilson.**—At St. Stephen's Church, Dublin, J. C. Hall, M.B., Monaghan, to Frances, only daughter of the late John Mason Wilson, Esq., of Harvest Lodge, Tipperary.

## Deaths.

**Baird.**—Feb. 17, at Linlithgow, G. Dallas Baird, F.R.C.S.Ed., aged 73.

**Clancy.**—Feb. 15, at Kilworth, co. Cork, J. Clancy, A.B., L.R.C.S.I.

**Copeman.**—Feb. 25, at Norwich, Ed. Copeman, M.D., F.R.C.P.Lond., aged 70.

**Davies.**—Feb. 17, at Dover, E. Pellew Davies, M.R.C.S., formerly of Christ Church, Hants, aged 66.

**Eddie.**—Feb. 21, at Barton-on-Humber, W. Healeden Eddie, M.R.C.S., J.P. co. Lincoln, aged 68.

**Fairbank.**—Feb. 26, suddenly, at Windsor, T. Fairbank, M.D., aged 37.

**Hannay.**—Dec. 11, at Nicaragua, Rbt. Strickland Hannay, M.R.C.S.E., aged 32.

**Harper.**—Feb. 20, at Killyleigh, co. Down, Hans Harper, M.D., in his 88th year.

**Stewart.**—Feb. 22, at 75 Eccles Street, Dublin, Eliza Stewart, widow of the late Henry H. Stewart, M.D.

## GULSTONIAN LECTURES ON EPILEPSY,

*Delivered before the Royal College of Physicians of London,*

By W. R. GOWERS, M.D., F.R.C.P.,

Assistant Professor of Clinical Medicine, University College; Physician to the National Hospital for the Paralysed and Epileptic.

### LECTURE III.

THE third lecture was devoted to pathology and treatment. Pathological anatomy in idiopathic epilepsy gives us little help. Regarding convulsions, however, pathological anatomy and experiment give us two sets of facts regarding the seat of the "discharge." Experiment shows that convulsions may originate in the medulla, from a centre near the respiratory. On the other hand, no local diseases cause convulsions so frequently as those of the cortex; and irritation of the cortical motor "centres" may cause convulsions, having definite modes of onset, like those sometimes seen in idiopathic disease. But other experimental facts make it possible that these convulsions, though excitable from the surface, arise in connected lower centres. Hence the latest writer of a systematic account of the disease, Rothnagel, with full knowledge of all pathological and experimental facts, concludes that epilepsy is a disease of the medulla oblongata. But the clinical study of modes of onset shows that at least many attacks commence in the hemispheres, viz., those of which the earliest symptom is a special sense or psychical aura. The clinical evidence that attack ever commence in the medulla is small. The "pneumogastric auræ" might be regarded as such evidence, but it may be present in attacks which certainly originate in the hemispheres. Such visceral sensations may accompany psychical auræ, as they do normal psychical states (*e.g.*, fear.) A curious case, however, was narrated, in which fits could be produced by passive movement of the spine, evidence of a probable origin in the medulla. The wide extent of "warnings" makes it probable that, as Dr. Hughlings Jackson has suggested, any of the grey matter of the encephalon which subserves sensori-motor processes may be the seat of the primary discharge in idiopathic epilepsy, but the evidence that the process of the fit commences in the hemispheres is much stronger and more frequent than that it commences lower down.

To explain loss of consciousness, vaso-motor spasm has been assumed, but the hypothesis is unnecessary, since the affection of consciousness may be the result of the discharge. Other evidence that vaso-motor spasm causes any of the symptoms is inconclusive. Pallor of face is not invariable, and does not necessarily show anæmia of brain. It may result from the cerebral discharge. To explain all the symptoms of attacks it is unnecessary to go farther than the instability of the grey matter in which the discharge begins.

This instability may be better understood as instability of resistance than as any increase in the energy-producing function of cells. The doctrine of internal resistance to action has underlain many current expressions as "nerve-tension," and its recognition gives us clearer views of many physiological and pathological problems. Thus we can understand why loss of blood causes convulsions, or a peripheral impression can arrest a fit, not for the moment, but for a long time.

The treatment of epilepsy, it was remarked, is a subject on which numerical analysis gives little help, because so many patients whose fits cease under treatment relapse when treatment is relinquished. The time available permitted little more than a statement of the remedies most useful in 562 cases in which the effect of treatment was carefully noted. The results showed that, while we must not rely *exclusively* on bromides, on these our chief trust must still be placed. Of the three alkaline salts the bromide of potassium deserves, as it has received, the first place. The salt of ammonium is more useful, only in proportion to the slightly greater quantity of bromine which it contains, while a careful comparison in a series of cases, between the salts of sodium and potassium showed that the former is distinctly less useful. The maximum effect of each dose of bromide occurs the sooner, the smaller the dose; hence small doses used to be given frequently. Bromide lessens reflex action, perhaps by increasing resistance in the centre, since it antagonises strychnia, which is believed to lessen resistance. If the view that unstable resistance is the chief element in epilepsy is correct, increase of resistance may be the explanation of the action of bromide. The mode of administration is usually by continuous course, in doses just sufficient to arrest the fits. Given thus it was rarely found well to give more than a drachm and a half daily; if this dose not suffice, combinations with other drugs answered better than increasing the regular dose. But it was urged that a course of large doses may be for a time employed, with a view of obtaining the full nutritive change in the nervous system, which bromide can effect. For this purpose it was thought best to give it in considerable doses, at longer intervals, beginning with half an ounce. The largest single doses given had been of one ounce, the doses being given at intervals of three to five days.

The value of the various combinations of bromide with other drugs had been tested by ascertaining first, during several months, the effect of a given dose of bromide, and then adding to it the agent to be tested. Of the combinations in common use, those with digitalis and belladonna deserve, as they have commonly received, the first place. Digitalis has enjoyed repute in epilepsy for two hundred years. Alone it sometimes does marked good, and in 63 cases the combination of digitalis and bromide was distinctly more useful than bromide only; in 37 of the cases the attacks ceased during the treatment. The effect of this combination is not confined to the cases in which there is cardiac disturbance, although in these it is almost always useful. Digitalis markedly increases the effect of bromide in nocturnal epilepsy. A case was mentioned in which a patient had not had a single fit for two years on the combination, although he had a fit at night every few weeks on bromide only. Belladonna alone will sometimes arrest attacks. The combination of it with bromide was distinctly more useful than bromide alone in 35 cases, and in 15 arrest of the fits was obtained. Indian hemp is now and then of marked service even alone. A case was mentioned in which the attacks always ceased on this drug, and recurred at once when bromide was substituted. Other combinations which had been found useful were bromide with aconite, and bromide with hydrocyanic acid. The cases in which the addition of iodide to bromide increases its effect are rare.

Zinc deserves some of the repute it has enjoyed for more than a hundred years. Of a large number of cases, in which the oxide was used in doses as large as the patient could bear it, it was diatinctly useful in ten, but in only three did the attacks cease. Bromide of zinc, in doses which could be borne, and the bromide of camphor, had seemed of small value. The addition of arsenic to bromide in no case had any influence on the fits, although largely used, on account of the certainty with which the bromide rash could thus be lessened or removed. Turpentine (recommended by Dr. Radcliffe) had been found distinctly useful only in hystero-epilepsy. The use of iron in epilepsy was discountenanced by high authorities. In some cases it seemed to increase the attacks, but in the majority in which it had been given its influence was distinctly beneficial. In four cases the attacks ceased on iron only; in eight others iron alone was distinctly better than bromide alone; and in nineteen the addition of iron to bromide had a marked influence; in eleven the attacks, which had persisted on bromide, ceased when iron was added, and remained absent as long as the combination was given. In several inveterate cases, in which bromide had little effect, the lecturer had given borax in doses of ten to fifteen grains twice or three times a day. In some it was useless, in some its beneficial effect was most distinct. Several cases were narrated in which the attacks ceased for a long time under its use. Occasionally it causes gastro-intestinal disturbance, but many patients bear it well. Cocculus indicus had not been tried sufficiently for an opinion to be formed, but very little benefit had been observed from its alkaloid, piciotoxine. The same conclusion was drawn from an interesting series of cases in which Dr. Ramskill had employed it hypodermically, which showed, however, that a dose of eighteen milligrammes will almost invariably produce a fit in from twenty to thirty minutes. Other drugs which had been tried and found useless were benzoate of soda and nitro-glycerine.

In hystero-epilepsy bromides, sometimes useful, often fail. Belladonna, iron, valerianate of zinc, and turpentine had appeared of greatest value. The treatment of the actual attacks of hystero-epilepsy is often a matter of difficulty. In the slight fits Dr. Pare's plan of closing the mouth and nose is often useful. When this fails Faradisation of the skin and cold douches on the head and water poured into the open mouth are often efficacious. Chloroform is of little value. Where all fail the lecturer had found the hypodermic injection of apomorphia invariably successful. After a twelfth of a grain had been injected, in four minutes all spasm was over, in six minutes the patient would get up, in eight minutes vomit, and then, except for slight nausea, be well.

In conclusion, the lecturer remarked that although the condition of many epileptics was still gloomy enough, yet the present generation had witnessed an advance in the treatment of the disease equalled perhaps in no other branch of therapeutics. Thanks to the influence of the drug the use of which in epilepsy was wholly due to Fellows of that College, hundreds of sufferers had been cured, and thousands were leading useful lives who would otherwise have been incapacitated by the disease. For all the victims of the disease we might surely trust that the progress of the recent past is the dawn of a brighter day.

## Original Communications.

### ON A REMARKABLE CASE OF CONGENITAL MALFORMATION OF THE RECTUM. (a)

By W. THORNLEY STOKER, M.D.,

Fellow, Member of Council, and Professor of Anatomy, Royal College of Surgeons in Ireland; Surgeon to the Richmond, Whitworth, and Hardwicke Hospitals, and to Swift's Hospital for Lunatics; formerly Surgeon to the City of Dublin Hospital.

On February 5th, 1878, I was consulted by a girl named Anne Fitzwilliam with reference to an abdominal tumour, for the treatment of which I received her into the Richmond Hospital. She was 21 years of age, unmarried, about 5 ft. 1 in. in height, of slender build, and with the exception of the bowel derangements hereafter to be mentioned, had always enjoyed excellent health.

On inspecting the abdomen an enlargement was visible which was as apparent as that observable in a pregnant woman about the end of the eighth month of gestation, but differing in its want of symmetry. A careful manual examination discovered a hard and heavy tumour, *which yielded a tympanitic note on percussion*, somewhat oval in form, with its long axis extending downwards and to the right, and occupying the following regions: the whole of the left lumbar, the upper part of the left iliac, the lower part of the left hypochondriac, and the greater part of umbilical, and top of hypogastric. It therefore lay chiefly to the left of the mesial line, extending 2½ inches above the level of the umbilicus, and below being traceable as far as the symphysis pubis beneath the level of the upper edge of which articulation it could be followed deep into the pelvis.

Careful measurement with a callipers gave the following diameters to the tumour, and in order to appreciate their great comparative magnitude, it is necessary to remember the small stature and slenderness of the patient:—

The tumour had pushed the uterus forwards and upwards, and it could easily be felt between tha wall of the abdomen and the smooth anterior surface of the mass. It could be exactly defined and moved from side to side by pressure.

The hollowness of the enlargement as evidenced by its percussion note, and certain facts elicited by questioning, at once made me suspect that in spite of its unusual size, I had to deal with a fæcal collection; and placing the patient on her side I proceeded to examine the bowel, and here a new and very interesting feature came to light.

I could not discover the slightest trace of an anus, and on introducing my finger into the vagina the reason was apparent, for the rectum opened on its posterior wall about 1½ in. above its orifice. The vagina was otherwise natural, if you except the facts that it was larger and more patulous than is usual in a virgin of normal development, and that it was elongated owing to the displacement upwards of the womb by the pressure of the tumour. The aperture of the rectum was round, had a thick edge, and was sufficiently large to admit one finger easily, or two with a little effort and the production of some slight pain. It did not appear to have any sphincter, and this was farther shown later on by the way in which fæces, at times when they were soft, passed into the vagina without the complete control of the patient. Some control she could exercise, but not as much as would be present if a sphincter existed.

The rectum passed a little below the level of the orifice, so as to form a shallow cul-de-sac, but was separated from the surface by a mass of tissue more than an inch in thickness, no rudiment of the natural opening being present.

The finger passed into the bowels discovered an indurated mass of fæces occupying it, the accumulation being also easily traced by the finger pressed upwards along the posterior wall of the vagina, where it made an oblong projection as large as a moderate-sized forearm its continuity with the abdominal enlargement could thus be followed and established.

The girl herself appeared ignorant of her peculiarity, or, at all events, of its exact nature, her mother having concealed it from her. She stated that she had suffered from constipation ever since her earliest childhood, her bowels only acting once, or occasionally twice, a week, and then generally under the influence of medicine, her usual and favourite drug being castor oil, which she habitually employed. For the last twelve months the above discharge had been still less frequent, once in a fortnight or three weeks being the average, and the intervals between the motions being at times much longer.

She suffered occasional griping pains for the five months previous to her reception into hospital. She had never noticed the "lump" until lately, but knew that her stomach was hard, and had felt the displaced uterus for the last four or five years; the latter observation showing the tumour to have existed for that period at least, as it was the cause of the displacement. She had never been sufficiently incommoded to oblige her to relinquish her employment, that of a parlour maid; and she had never suffered from jaundice, œdema of the lower extremities, or any other intercurrent complaint.

The nature of the case was now perfectly evident; in addition to, and dependent on, the malformation of which the patient was the unhappy subject, there existed a fæcal collection of most enormous dimensions, engaging the rectum and at least the whole of the sigmoid and descending colons; but its position towards the left side, its shape, the inclination of its axis, and the absence of any jaundice, pointed to the freedom of the upper part of the great bowel.

The question now arose how was this great collection to be removed. As she suffered from no symptom of obstruction except constipation, which at the time of her admission had lasted some weeks, and as the tumour gave a distinctly tympanitic sound when percussed, it was easy to understand that it was hollow, and afforded a receptacle in which each addition of fæces was received, and was being stored up. I therefore sought in the first instance to "uncork," as it were, the lower end of the mass, and for this purpose on two occasions introduced my index finger and Crampton's spoon into the rectum through the vaginal orifice, and removed as much hardened fæces as I could. I may say, however, that owing to the difficulty of approaching a rectum more removed from digital examination than would be the case in an ordinary person, the process of scooping the fæces was not attended with much success, and the quantities I removed were small. I was able, however, to break up the lower end of the mass, and to some extent free the exit. I found greater benefit result from enemas and purgatives. Of the latter several varieties were employed alternately, including calomel, sulphate of magnesia in combination, castor oil, and compound senna mixture prepared with carbonate of potash, the latter having the best effect, and in alternation with occasional doses of castor oil being that on which I mainly relied. The purgatives acted so well that I found the use of the enema necessary only at intervals, about half-a-dozen lavements of warm water being employed during her treatment, the bulk of each being from two to three quarts or more. The long tube was used and was readily introduced on the index finger as a guide. It required a slight amount of gentle force to get it through the mass which filled the rectum, but when past this point the facility with which it could be pushed into the bowel was remarkable; it passed for its whole length without resistance into the hollow interior of the tumour. Those who have used O'Beirn's long tube are aware that its whole length can but seldom be introduced, especially with so much ease.

Under the influence of this treatment large motions were passed frequently.

One day while manipulating the abdomen I felt the mass yield under the pressure of my fingers, and on using some cautious force I broke up the whole collection, now reduced to a shell. After this time increased quantities of excreta passed away under the influence of the purgatives; the bowels began to show a tendency to unassisted action. She was put upon a course of belladonna, and finally left the hospital on March 20, 1878, that is, 44 days subsequent to her admission, with her bowels acting as naturally as her deformity permitted, and with no evidence of hardened fæces remaining. I have seen her since, and she remains in excellent condition. I may add that care was taken not to procure too rapid a discharge of the contents of the gut, so as to allow time for its contraction and return to a state of health.

This case affords two points of interest; one, the size and circumstance of the collection of fæces; the other, the nature of the malformation which was its cause. In reference to the first it is to be said that but seldom do intestinal collections attain such a size as this, and when they do it is usually in much older persons. I can only in my own practice recall one case parallel to it in respect of this, that of a very old lady whom I saw some months later, and in whom, from neglect and without any mechanical cause existing, a much larger collection had taken place. Her case had not been diagnosed correctly—had received no adequate treatment, and when I saw her any remedy was too late, as she was at the point of death. She had a hard fæcal collection which filled the whole of the centre, lower part, and left side of the abdomen and the rectum. She had not had a sufficient movement for many months, but there was not complete obstruction, a channel of small size evidently remaining through the centre of the mass, and the lady dying exhausted without any signs of the bowels being completely occluded.

It was remarkable in the case of A. F. that the retention must have existed for at least four or five years, and must during that time have formed a mass sufficiently large to displace her womb, and yet her general health was good, and she really suffered but little. I doubt indeed if she would have demanded treatment but for the way in which the "lump," as she called it, spoiled her figure, she being a young person who thought much of such matters. Every one who has had medical experience of the lower classes in this country must have been often surprised at the extent to which disease is allowed to progress unnoticed or uncared for, and yet he would find it difficult to understand how a patient such as this, who was above the ordinary peasant in refinement and intelligence, could allow herself to arrive at such a condition without seeking advice.

Bodenhamer in his work upon Malformation of the Rectum and Anus has classified them into nine species, and this case comes into his sixth class, which he defines thus :—"This species is recognised by the rectum terminating by an abnormal anus, either in the bladder, the urethra, the vagina, the uterus, or in a cloaca in the perinæum with the urethra and vagina. There is generally neither a natural anus, nor the sign of one present."

Of all the varieties of malformation included in this class that which is least rare is the form of which I present an example to the Society, and it is of particular interest, inasmuch as it is the least destructive to life, and is that which affords most hope of relief by operative procedure. Of the others, that which is most unusual is where a cloaca exists into which the rectum and genito-urinary organs open in common, as is found in birds, reptiles, monotremata, and in some fishes. Of commoner occurrence is the opening of the bowel into the bladder or urethra, a condition more generally found in the male than in the female, and when existing in the sterner sex, so unfavourable in its result, and so little amenable to interference, as to have obtained from some surgeons the undeserved character of being rapidly and universally fatal.

When the rectum terminates in the vagina the opening is usually solitary, although one or two cases of a dual aperture are on record, and is—as in my patient—situated low down on the posterior wall, and the opening is sufficiently large to admit one or two fingers, although at times much more contracted. The rectum as it approaches its vaginal orifice is in some instances gradually narrowed, but is oftener of tolerably full size. When the latter state exists it should always be carefully examined to discover if it does, or does not, extend nearer to the surface of the perinæum than its point of opening, for if it does, a sort of cul-de-sac is formed, which was present in my case, and which materially facilitates operative interference.

When the disgusting nature of this deformity is remembered, the state of filth in which the patient is kept, the irritation of the vagina from the presence of fæces, the mental and moral depression which such a condition should induce, and the habitual constipation which generally resists the unassisted efforts of nature (the bowels in the majority of recorded cases only acting on an average every seven or eight days), it is not wonderful that the question of relief by operation has been anxiously considered, and has been carried out, although, as I have said, life is not generally endangered by the malformation, many of the recorded cases being those of adults, some of them having become pregnant and borne children, and one mentioned by Mercurialis and attested by Morgagni having survived to the age of a hundred years.

Putting aside the palliative measure of dilating the opening of the bowel by bougies in cases where it is much contracted, there are, speaking broadly, two plans of operating, the aim of both being to close the orifice in the vagina, and establish one in the normal position in the perinæum. In the older of those proposed by Vicq d'Azyr, and modified by M. Martin, the whole of the posterior wall of the vagina below the opening is incised with a bistoury from before backwards, cutting as far towards the tip of the coccyx as may be necessary to allow room for the introduction of a silver canula, reaching from the surface to the rectum, in front of which the divided tissues are then brought together by points of suture, the instrument being left *in situ* until the edges have united and the new passage is established. This operation has been recommended to be modified by the omission of the sutures, their introduction being extremely tedious and difficult, and union probably taking place in front of the canula as well without them.

The second operation is that of Velpeau, who objects to the division of the posterior vaginal wall, and directs an ordinary blunt hook to be passed backwards through the recto-vaginal orifice and pressed downwards, so as to cause the tissue of the perinæum to project in the situation where it is desired to form the new opening, which is then made by cutting upon the end of the hook, and enlarging the incision with a probe-pointed bistoury, so as allow the introduction of a canula into the intestine. The vaginal anus is then revivified, and its edges brought together.

There can be no question that of the two operations, of both of which there are slight modifications, that of Velpeau is much preferable, as it avoids the division of the recto-vaginal septum. It is obvious, however, that it could only be undertaken in cases such as mine, where the bowel terminated by a cul-de-sac, and that in instances where this is absent, and where the rectum contracts to a funnel shape, with its apex at the vaginal anus and without any cul-de-sac at its termination, the plan proposed by Vicq d'Azyr is that on which we must rely.

I am not as yet without hope that my patient may submit to an operation, but up to the present she has not consented to do so. If she does I shall bring the result under the notice of our members.

◆

## EPITOMISED ACCOUNT OF A CASE OF LARGE RANULA, ACCOMPANIED BY A TUMOUR WHICH OCCUPIED THE WHOLE FLOOR OF THE MOUTH. (a)

By W. I. WHEELER, M.D., M.Ch. Univ. Dub.,

Fellow and Member of Council Royal College of Surgeons, Surgeon and Lecturer on Clinical and Operative Surgery to the City of Dublin Hospital.

The communication which I bring before the Society will be very brief, and will merely detail the history and treatment of a case most interesting and unusual.

A. G. was admitted under my care into the City of Dublin Hospital on the 19th October, 1879 (recommended by my friend, Dr. Charles Lyster, of Kilkenny), suffering from a large ranula, complicated with a tumour occupying the floor of the mouth. The usual signs of ranula were present, better marked, however, than the generality of cases. A tumour about the size of a Seville (bitter) orange was evident beneath the symphysis menti, the tongue was raised at its extremity, and the entire under surface pushed up by the tumour before alluded to. As far as I could ascertain from the patient, the ranula was of about one year's duration, but she was not aware of the existence of the second growth. Careful manipulation showed the tumour and ranula to be quite distinct, indeed the appearance caused by the latter beneath the chin gave one the idea that a calculus was obstructing "Wharton's duct." On the 28th of October I excised a piece from the cyst of the ranula beneath the tongue ; glairy fluid flowed, and after a time about a teaspoonful of dark thin fluid came ; pressure on the swelling beneath the inferior maxilla caused an increased flow, and all signs of the ranula disappeared. Notwithstanding that a large piece of bone was removed from the ranular cyst, it filled again, its closure being favoured by the pressure of the tumour from behind. My intention now was to cure the ranula, and remove the cyst occupying the floor of the mouth at the same operation.

On Sunday, the 16th November, I saw the girl at 11 o'clock a.m. She was in her usual health ; the swellling beneath the chin was not quite so large as when she was admitted; she ate her breakfast and dinner as usual, and attended her place of worship—in fine, in her usual health. At 8.30 p.m. on this evening I was summoned to see her, and arrived at the hospital about nine o'clock. She was suffering from intense dyspnœa, her eyes starting from her head, countenance anxious and distressed, cold perspiration on her face and body. Sitting up, she grasped the bed clothes like one suffering from asthma; her tongue was enormously enlarged, and pushed upwards and backwards; both tumours had enormously increased in size; her pulse was rapid and weak; and one unaccustomed to such scenes would have said dissolution was near at hand. Dr. Batt, medical resident, in the absence of the house surgeon (Mr. Patten), made an incision in the dorsum of the tongue, on the left side. On my arrival, I made another on the right of the raphe. This did not give much relief. I then rapidly opened up the cyst of the ranula beneath the tongue and made an incision into the enlargement externally. From both fluid escaped. Much benefit was derived from this; and next I ripped open on each side the tumour beneath the tongue, and scooped out some of its contents. This gave great ease to the patient, and being now able to feel the epiglottis, which was œdematous, I scored it with a small curved knife. The patient had poultices and warm fomentations applied, she also inhaled steam; and now, for the first time since she was so urgently attacked, was she able to swallow about half a teaspoonful of milk, the most of the liquid returning when she attempted to do so. Nutritive enemata were given, and she got some sleep during the night. The next day, not being as much benefited as I expected, I opened into the floor of the mouth from without, and evacuated the remainder of the contents of the tumour beneath the tongue, which was of a cheesy consistence. There was some hæmorrhage, which was controlled. Mr. Tufnell was present and assisted, as also Mr. Patten, the late house-surgeon, and Mr. Ashe, his successor.

---

(a) Read before the Surgical Society of Ireland.

On the next morning I removed a considerable portion of the cyst through the external opening and through the mouth. Suffice it to say, this case terminated in complete cure. She left the hospital on the 5th December, 1879.

I have epitomised this paper purposely, and not gone into any descriptions of acute ranula, which possibly the case might have been mistaken for had it only been seen for the first time. I have seen two cases of acute ranula, the most urgent symptoms coming on within an hour and a-half, the patient being in perfect health two hours before the most distressing dyspnœa supervened. The only case recorded which seems to me at all to resemble the above is one described by the late Sir Wm. Fergusson in his "Practical Surgery."

## DIPHTHERIA CONVEYED BY POLLUTED WATER.

By JOHN MOORE, Esq., M.R.C.S.

Communicated by JOHN THOROWGOOD, M.D., F.R.C.P.

IN the village of Bourton-on-the-Water in Gloucestershire, in 1862, the first case of diphtheria was seen by Mr. Moore in one of a number of cottages, the drainage from which was conveyed by a ditch into the watercourse running west through the village.

The inhabitants of the lane obtained their water from a pump in the centre of the lane. In consequence of this pump being temporarily useless, the people were compelled to obtain their water from the watercourse or better termed ditch. About one week after the appearance of diphtheria in the cottages referred to, the disease broke out with much virulence amongst the children in the neighbouring lane. There were thirteen cases, six of which were fatal, in the course of ten days.

The children who were thus affected got the water from the polluted ditch which received the drainage from the cottages, distant a good quarter of a mile.

# Transactions of Societies.

## HARVEIAN SOCIETY OF LONDON.

MARCH 4TH, 1880.

The President, HENRY POWER, Esq., F.R.C.S., in the chair.

### RECURRENT TUMOUR OF THE EYE.

The PRESIDENT related the case of a woman who came under his notice first with a tiny melanotic speck on the eyeball. He removed it, but it returned. It was removed a second time; it then reappeared as a pink tumour with a malignant appearance. The whole ball of the eye was then removed. In a few weeks it returned as a small button at the bottom of the orbit. This was removed, and the patient remained well for eight or nine months, when it reappeared again, and was once more removed. She remained well for eight months, when she returned with a large melanotic tumour protruding from the orbit. This was thoroughly removed, after which she lived two years, dying of cancer of the abdomen, but without return of the original disease.

Mr. SEWILL spoke.

Dr. PERCY BOULTON on

### TYPICAL DEVELOPMENT OF CHILDREN, OR THE BEARING OF ANTHROPOLOGY TO HYGIENE.

From observations extending over ten years, Dr. Percy Boulton said that anthropology in its non-medical aspect is a most valuable aid to preventive medicine. During the period of growth the scales and measures used systematically render arrested growth at once evident, and this is a certain forerunner of disease. The age standard is most fallacious, and the only trustworthy measure of healthy development is weight for height. The reason for this is that perfectly healthy children grow at different rates per annum, which accounts for different adult heights amongst perfectly healthy people. Two inches a year is the lowest rate between three and five feet that is consistent with typical development; so that any child growing less than two inches a year should be looked upon as suffering from some drawback to healthy development, which, if discovered, is probably removable. The most common causes are unsuitable or insufficient food, over-work, mental or bodily, want of proper rest, &c. Few children grow *more* than three inches a year, and such require careful watching, as it is a rate of growth scarcely consistent with safety. Those growing over three inches a-year would require more food and rest. They are easily fatigued, and should not, therefore, be allowed to take violent exertion of any kind. Two, two and a-half, and three inches a year may be taken as the normal rates of growth of healthy children with suitable surroundings. The first prognosticates short, the second medium, and the third tall adult stature. Growth should be regular, not by fits and starts, and hence the child that grows two inches a year is about five feet at fifteen years, whereas the child that grows three inches a-year is five feet at ten or eleven. Variation in rate of growth explains perfectly differences in height, and at the same time shows the fallacy of an age standard. Weight for height in all cases should be the same. As a standard of weight for height is absolutely necessary, Dr. Boulton, has drawn up a table taken from ten years observation of a large number of the healthy children of well-to-do parents, brought up with suitable food and surroundings, giants and dwarfs being excluded. He will be happy to forward one to any one applying to him by post. The standard is that of typically healthy children. It is found that such may fall seven pounds below the standard before entering what Dr. Boulton called "the land of Cachexia." Children that always weigh seven pounds below the standard have no capital to draw on, and quickly succumb to constitutional diseases. It should be our aim to keep growing children up to the standard, as then there is a seven pound preventive medicine margin. By frequent weighing and measuring, loss of weight, which is such a frequent forerunner of disease, would be detected at once, and become a valuable danger signal. Several suggestions were then thrown out for the physical improvement of the people.

The President, Dr. Day, Messrs. Malcolm Morris, Mason, Alderson, and Osman Vincent spoke, after which Dr. Boulton replied, and the meeting adjourned.

## SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society was held on Friday evening, February 13, in the Albert Hall, Royal College of Surgeons, Dr. McCLINTOCK, Vice-President of the College, in the chair.

Mr. B. WILLS RICHARDSON, hon. sec., read the minutes of the previous meeting, which were signed.

### MORBID SPECIMEN—AMPUTATED ARM.

Mr. HENRY GRAY CROLY exhibited the arm of a woman, æt. 70, he amputated on the previous Tuesday. She was admitted into the City of Dublin Hospital on the 8th of last January. She had a very large and evidently malignant ulcer on the lower part of the forearm. About eight years ago she noticed a small wart on the region where the disease became seated. Consequent on the disease the radius was fractured and the ulna projected, the dislocation of the lower end of it presenting rather a remarkable appearance. No glands were enlarged, except in the vicinity of the elbow-joint. For a woman of advanced age she seemed to be in general good health. There was no visceral disease that he could ascertain. The special form of cancer the one in question belonged to he would not venture at present to determine, pending the result of microscopic examination of some sections made of it by Mr. Abraham, curator of the museum.

Mr. W. THORNLEY STOKER read a communication on a case of

### CONGENITAL MALFORMATION OF THE RECTUM,

which will be found at page 186.

Dr. CRANNY mentioned a case that came under his notice in the Rotunda Hospital. A woman was delivered of a child, and she had the same malformation Mr. Stoker had described. At the time he did not examine to see whether or not there was a *cul-de-sac* rectum; but she seemed unaware of there being anything wrong with her, and did not suffer any inconvenience.

Mr. W. WHEELER said the communication just read reminded him of a paper written by Mr. Curling some ten or eleven years ago, giving an account of one hundred congenital malformations of the rectum, and showing the large proportion of males that suffer from this deformity in comparison with females. In the 100 cases, only 11 were afflicted with the rectum opening into the vagina, although 32 female cases were quoted, proving the deformity brought before the Society to be an unusual one. He had himself seen several cases of congenital malformation of the rectum. On one he operated successfully. There was one case of this deformity which he brought before the Society in 1878. It was a very unusual one and was reported in his paper on "Deformities of the Bladder," in the *Medical Press* of February 6th :—

"I may here mention a curious deformity which lately came under my notice, namely, a case of spina bifida with the intestine opening by its side and fæcal matter discharging. I saw the case with Dr. Byrne, of Baggot Street, and had an opportunity of showing it to Dr. Hawtrey Benson. The child died, but a post-mortem would not be permitted."

The paper then proceeded to relate a case recorded by Bartholin in which there was neither penis nor anus, and all the ingesta returned by the mouth for more than fifty years. By drawing a diagram he could, he thought, be better understood, and show what exactly is the cause of these deformities, and especially the one Mr. Stoker had brought before the Society. Mr. Wheeler then drew a diagram of a fœtus, about 10 days' old, showing the relative position of parts where the allantois was placed, and how the epiblast invaginated to meet the hind portion of the hypoblast and thus form the rectum, and that when this invagination did not take place, the rectum would open into the invaginated portion of epiblast in front, in fact the vagina; of course the deformity might take place from inflammation during intra-uterine life. Independently of colotomy there appears to be two forms of operation suitable to the class of cases Mr. Stoker brought forward—the enlargement of the existing outlet, and the formation and establishment of an anus in the normal position. Now that enlargement at all events was absolutely necessary was evident to all who had read the paper he had alluded to, as it distinctly stated that death had been caused by over-distension, and curiously enough, a case came under his notice that evening of the rectum opening into the vagina in a child, 3½ years old, who had to be placed in a warm bath whenever the bowels were being moved, he presumed to assist in the movement. He could not concur with the opinion that it would be well to close the opening in the vagina directly the formation of an anus in the normal site was accomplished. On the contrary, it was found from experience that this opening somewhat contracted or diminished in size, and thus rendered it easier for future operative interference. Nor was an operation for this kind of deformity one very likely to be followed with success, and especially in adults, for although the retentive powers of the bowel may exist sufficiently, the muscular coats of the rectum were generally hypertrophied and the mucous follicles enlarged, and the expulsive powers of the bowel weakened, so that the afflicted one suffered much the same as if stricture existed. The commonest cause of death after operative procedure appeared to be from wound of the peritoneum causing inflammation of that membrane.

Dr. ATTHILL cited a case which occurred in his practice three months ago. A woman was delivered of a healthy child apparently well-formed, but on the day after its birth the nurse told him it was malformed, having no anus. However, he diagnosed an imperforate anus. At the same time he told the father the child was not likely to survive. Next morning there was a natural motion; and he found the anus opened into the vagina a little way up. He fell into the mistake, and others might do the same, of attempting to make an artificial anus where there was an opening into the bowel; but as he saw no symptom of a termination of the rectum he did not attempt an operation, though he had before now done so. He thought, therefore, having regard to the foregoing case, where there was a deficiency of the anus in the female infant the vagina ought to be carefully examined before performing an operation. It was quite possible he had been misled by the fact that there was no attempt at defæcation. The difficulty would be much more considerable if the rectum terminated in a pouch; and if the case were considered one of total occlusion of the anus a purgative would not be given.

Dr. J. A. BYRNE regarded the description of the anatomical arrangements of the parts and the diagnosis of the tumour as of very great importance. Had the case fallen into less scientific hands, it would probably have been pronounced one of ovarian tumour. Mr. Wheeler having referred to male deficiencies of the rectum, he thought he might mention a curious case in his own practice—that of a child four or five days' old, who having passed nothing by the bowels, was sent up from the country to Vincent's Hospital. Late on a Sunday night he endeavoured to make an opening into the rectum with the assistance of the resident surgeon. There being no indication whatever of an anus, he made a crucial incision, passed in catheters, probes, and directors fully an inch in depth, and could find nothing. This was the second case of the affection he had seen. The other he saw with Surgeon Hutton in the case of a lady who gave birth to a male child. In operating he passed a bistoury into the bladder; a quantity of urine came away, and the child died in a few hours. He also saw a case when the Vice-President (Dr. McClintock) was Master of the Rotunda. In that instance it was a mere septum across the rectum. The anus was perfect. On making a slight incision into this, which was rather of a dense nature, the fæces escaped and the child recovered. In the recent case to which he referred they performed the posterior operation on the following day, assisted by the President of the College (Dr. Mapother), but the result was unsuccessful. There was great difficulty in arriving at the intestine, being very small and undeveloped. They did not reach it. But what was remarkable about the case was this, that they were very near success, because next day, on making a post-mortem examination, they found that had they penetrated a quarter of an inch farther they would have got the end of the rectum. The rectum did not stop at the ileo-cæcal termination, but went half-way down the anterior surface of the sacrum, and stopped within three-quarters of an inch of where the anus usually was. It was not pleasant to record unsuccessful operations; but he did so *pour encourager les autres*, as he would not hesitate again to pass on the bistoury.

The Vice-President mentioned that a few years ago he was asked by Dr. Sibthorpe, of Hume Street, to see a female child two days old. Great anxiety was felt on account of its not having any evacuation from the bowels. There was no sign of an anus whatsoever, and the question of puncture and so forth was considered. However, though he did not know what prompted him, he took a large silver catheter, passed it into the vagina, moved it round freely, and to his surprise and satisfaction a quantity of meconium came away from the vagina at once. There was a small communication high up, and the instrument had opened this, or displaced some thick, intercepting matter in the vagina, and allowed the meconium to come away. He explained the nature of the unfortunate communication to the family, but mentioned that it was not necessarily fatal. He had reason to believe the child survived, or was certainly alive some months afterwards. Under similar circumstances it was worthy to be borne in mind, before coming to the conclusion that there was no natural vent from the rectum, an examination of the kind should be made.

Mr. W. Thornley Stoker, in reply, said the case he recorded was not meant, as some seemed to imagine, to be at all a comprehensive treatise on the subject of deformities of the rectum. He had, of course, seen a good number of cases of malformation of the rectum, chiefly in young children, and he had operated in two or three, and all the cases he had seen, except the adult one now recorded, occurred in male infants. The result of his operations had been uniformly unsuccessful—he never had occasion to interfere with the malformation of the rectum that the patient did not, sooner or later, die. In one instance he failed entirely to discover the bowel. An observation had fallen from Dr. Byrne in reference to the possibility of injuring the bladder. In any case in which he operated, being aware of the propinquity of the rectum and the back of the bladder, he introduced a catheter and avoided as far as possible any danger of opening into the urinary bladder. In reference to Mr. Wheeler's remarks, Mr. Stoker said he did not intend to introduce the question of the cause of those deformities, which was a subject so extensive, that instead of being incidentally introduced as a paragraph in a practical communication, it would require a very lengthy paper to itself.

Mr. William Wheeler read a communication on a

### LARGE RANULA, ACCOMPANIED BY A TUMOUR WHICH OCCUPIED THE WHOLE FLOOR OF THE MOUTH, ONE BEING DISTINCT FROM THE OTHER,

which will be found at page 188.

Mr. Tufnell said he saw the case. The ranula was of a very chronic character, and the contents expressed and removed were quite sebaceous. Inflammatory action supervening on the pre-existing state led to the symptoms which required the active treatment. The *materies morbi* contained in the cyst was such as he never saw in any other case, being perfectly cretaceous, and almost as hard as mortar.

Dr. Henry Kennedy said the case recalled one brought forward by the late Dr. Montgomery, as he quoted the sentence "*Magna pars fui.*" Dr. Montgomery had presented a stone of the size of a filbert nut, which had formed under his own tongue. It grew rapidly within two months to the size of a filbert-nut, and was removed with comparative ease from the duct by means of a small pair of forceps. However, it was remarkable that the tumour should have grown so rapidly and become a regular calculus, the composition of it being of the cretaceous character found in cases of the sort. In reference to the case under discussion, there must have been some nervous or inflammatory irritation going on when the patient was admitted to hospital, and any additional cold would naturally spread to the epiglottis and give rise, in the female particularly, to the very urgent symptoms described. The treatment in such cases was obvious. Leeches had been found exceedingly beneficial applied to the tongue in large numbers. For his own part, an incision would be preferable. He asked whether there were not two tumours—one on one side and the ranula on the opposite side of the tongue?

Mr. Wheeler, in reply, said the ranula had not any communication with the tumour on the floor of the mouth. Referring to Dr. Kennedy's observations, he said he made an incision beneath the symphysis menti under the tongue and each side of the tongue, through the cyst of the tumour occupying the floor of the mouth, and that he afterwards opened into the mouth from without beneath the chin.

The Society then adjourned.

## ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

Wednesday, February 18th, 1880.

W. A. N. Cattlin, F.R.C.S., President, in the chair.

After the annual address given by the President, on which we commented in our last,

Mr. Hamilton Cartwright opened a discussion

### ON THE MEANS OF DIAGNOSIS AFFORDED BY AN EXAMINATION OF THE TEETH AND MOUTH IN DOUBTFUL CASES OF CONSTITUTIONAL DISEASE.

He desired to show how some knowledge of dental lesions might be of the greatest service to practitioners in medicine and surgery, whilst, at the same time, the qualified surgeon practising dentistry might give valuable aid to his *confrères* in many dubious cases. The first subject he wished to draw the attention of the Fellows to was that of neuralgia, connected more especially with the head and neck, which he divided into supra-orbital, infra-orbital and facial, mental and cervico-facial. His contention was that there is no such disease as idiopathic neuralgia; that a cause for it is invariably to be found, whether it be in connection with the impressions created on the nervous centres by the ovum in the womb, or by the diseased tooth. He then combated the theory that in ordinary cases there is any degeneration of the *posterior* roots of the spinal nerves, proving his hypothesis by many examples of sudden and complete cure on the removal of an exciting cause of pain. Though the teeth were very frequently the originators of a spurious kind of neuralgia, he thought that they were very often unjustly blamed and sacrificed. In speaking of the *loci* of neuralgic pain, he hazarded the theory that the symptoms of neuralgia were in no small number of instances owing to pressure on the main branch of a nerve, caused by exostosis around the edges of the foramina through which they pass. He then gave the means of diagnosing between pain due to dental causes and that caused by lesion of the nervous centres, or by that of special nerves, maintaining that by a process of elimination it was easy to prove whether the teeth were at fault or not. He then alluded to the subject of gout, showing that there was a special condition of the teeth and oral mucous membrane by which the disease might be diagnosed, and even anticipated in hereditary cases. He then entered upon the signs of syphilis seen in the mouth, as those of rickets, phthisis, and dyspepsia, concluding an exhaustive discussion with the signs of scrofula and struma in the glands, laying great stress upon the fact that a lack of knowledge of the elements of dental surgery, such as might be acquired in any general hospital, frequently was the cause of glandular abscess being treated as scrofulous, and which were entirely owing to causes connected with the teeth.

The President thanked Mr. H. Cartwright for the clear and able manner in which he had brought a very interesting subject before the meeting, and quoted several published cases in support of the theory that the local cause of facial neuralgia was often to be found in a remote part, and *vice versa*. He instanced the case published by Sir Charles Bell, in which an ulcer of the stomach had caused facial neuralgia, and others mentioned in Sir Henry Halford's Essays, in which osseous deposit on the crista galli of the ethmoid bone had produced the same effect. Perhaps the most interesting cases he could refer to of pain in remote parts produced by irritation of the pulp or nerve of a tooth, was one published by the late Mr. Sercombe, in which severe spasm of the uterus was clearly traced by experiment to the exposed pulp of a tooth. He thought facial neuralgia was more frequently to be traced to the gouty diathesis, and an anæmic condition of the blood than Mr. H. Cartwright supposed, although cases of neuralgia from constitutional causes were by far the most rare, and Dr. Fothergill had shown that they were common in malarious districts.

Mr. Francis Mason dwelt upon the importance of distinguishing syphilitic from other diseases of the cavity of the mouth, and remarked that the commonest form of secondary eruptions in that cavity was found in a raised whitish patch somewhat indented from contact with the teeth, and situated inside the cheek near the angles of the mouth on both sides.

He believed that in the true syphilitic sore-throat such patches were observed either over the tonsils, or extending as crescentic elevations on the soft palate. If the tongue were affected the patches were chiefly on the sides of the organ, and indented from contact with the teeth. He believed that this peculiar raised condition, due to the effusion of lymph so characteristic of true syphilis, was much more commonly to be observed than the deep excavated ulcer. He further remarked that it was customary at the present day to attribute all cases of exfoliation of the palate and nasal bones to syphilis. His own experience led him to believe that in by far the majority of such cases there was no history whatever of true syphilis.

The **President** assumed that Mr. Mason attributed necrosis of the bones of the nose and other parts more to the abuse of mercury than syphilis, although he had not actually said so.

Mr. **Mason**, in reply to the President, coincided with him that the awful destruction of the bones of the face and soft parts, as occasionally seen in former years, but now, happily, illustrated only in our museums, was due not to syphilis, but most probably to the wholesale administration of mercury for its supposed cure. Lastly, he urged the importance of making a correct diagnosis, and instanced some cases in which the mere eruption of a wisdom tooth had been mistaken for syphilitic sore throat, and had been treated accordingly.

Mr. **Edgelow** considered that neuralgia had always some positive cause, and narrated a case that had come under his notice at St. George's Hospital, in which exostosis of the fangs of a tooth had caused severe pain in the hand, which subsided at once on the extraction of the tooth.

Mr. **Ranger** stated that in two cases which he had recently met with at St. Thomas's Hospital the same result followed. The first case was that of a young man who suffered extreme pain in the right arm and down to the hip-joint. He found a lower bicuspid very much decayed, and on destroying the pulp with arsenic the pain ceased almost immediately. The other case was that of hysteria in a girl, when, on removing a lower bicuspid, much decayed, the same result followed.

Mr. **Hamilton Cartwright** briefly replied.

# Special.

## FRANCE.

[FROM OUR OWN CORRESPONDENT.]

Paris, March 4.

The death-rate of Paris during the last two months has been exceptionally high. For the first week of the month of January the mortality was 1,294, increasing in every succeeding week to the first week in February, when it stood as high as 1,619 (the average of the corresponding weeks of the three preceding years having varied between 956 and 1,062 as maximum). This abnormal increase may be no doubt attributed to the exceptionally rigorous winter on the one part, and to the slight epidemics of small-pox and typhoid fever which have reigned amongst us for the past six weeks. No new special disease has been observed which could be attributed to the cold, nor any appreciable modification in the character and course of ordinary diseases save a considerable increase in cases of frozen extremities and erythema. In the month of January the number of fatal cases of small-pox was reported as 280, diphtheria showing 164, and typhoid fever 89, but this latter for the first week of February alone increased to 101.

A special commission is being formed by the Minister of Public Instruction for the revision of the French Pharmacopœia published in 1867 by the Government. A new edition is to be prepared.

Professor Paul Bert gives a short *exposé* of his anæsthetic (a mixture of protoxide of azote and oxygen under pressure) in the *Gazette des Hôpitaux.* He claims for it the following advantages :—1st. An immediate return to sensibility and a perfect *bien être.* 2nd. Absolute tranquillity, not only of the patient, but of the operator, as there is no vomiting nor irregular breathing observed as a result of the inhalation of the protoxide of azote ; and the third advantage is that relative to the state of excitement which is often so troublesome and sometimes dangerous with chloroform. With M. Bert's agent nothing of the kind occurs save sometimes a little rigidity, which is always easy to master. The patient passes, so to say, *brusquement* from consciousness to insensibility. If one added to this the considerable number of observations furnished by American dentistsrelative to the employment of *pure* protoxide of azote, one might with all safety affirm that this method was absolutely without danger. However there is, according to the Professor, one inconvenience attending the administration of this anæsthetic agent. A room whose walls are strong enough to bear the pressure is indispensable. Consequently the application of this procedure is rendered impossible on the field of battle.

A doctor at Val de Grâce has just died a victim to his devotion. A patient in the hospital to which the medical man was attached was on the point of death, and transfusion was proposed as a *dernière ressource.* The doctor in question offered his blood, which unfortunately for him was but too readily accepted, for a few days afterwards purulent pleuritis set in and carried him off.

## THE PROPOSED METHODS OF "DIRECT REPRESENTATION."

In discussing last week the general proposition of the reconstitution of the General Medical Council, we suggested four methods by which that body might be liberalised and improved : —

1. To reduce the number of representatives of licensing bodies by disfranchising peremptorily those bodies which have no considerable share in medical education or qualification, and no special function as qualifying bodies to

fulfil; *e.g.*, the Apothecaries' Companies of London and Dublin, and the University of Durham, and perhaps the Glasgow Faculty.

2. To cause the Crown nomination to be exercised more frequently in favour of distinguished working practitioners rather than exalted metropolitan doctor-princes.

3. To add to the Council a fair proportion of representatives directly elected by the rank and file of the profession.

4. To transfer the election of the representatives of licensing bodies from the executive councils, lay convocations, and nominated senates, to the medical corporate members of such licensing body.

The two Medical Bills now before Parliament—that of Mr. Mills, representing the British Medical Association, and that of Dr. Lush, representing the Medical Alliance Association—agree in the principle of direct representation, but propose different methods of attaining that object, while the Government Bill does not make any attempt whatever at improving the constitution of the General Medical Council.

Before proceeding to contrast the two methods of reconstitution which are suggested, we may at once clear the ground by declaring on behalf of the profession at large, that reconstruction of the Medical Council is a matter upon which they take their stand, and that no Bill which fails to provide for a thorough reform in this respect can be allowed to pass, or, if carried in spite of their opposition, can be allowed to stand as a final settlement of the matter. Upon this determination there ought to be no misapprehension, nor should there be any compromise, and those who speak on behalf of the profession before the Select Committee ought to make it perfectly clear that any or every Bill which entrusts the medical education and qualification of the future to the Medical Council as at present constituted will be resisted with vigour, and if passed, will be attacked every year until the needed reconstitution is effected.

While asserting this determination on the part of the profession at large, we are not to be taken as implying that medical men are half-hearted about the question of medico-educational reform, which is the other great purpose of the proposed medical legislation. We thoroughly appreciate the extent to which the abuses of medical education and medical licensing have been allowed to run by the Medical Council, and we do not under-estimate the extreme importance to the profession and the public of a reform of these abuses. On the contrary, every medical man has personal knowledge of the ill results which have accrued from the admission to our profession of half-educated persons of low social grade by the uncontrolled selling to them of cheap and easy diplomas by needy and greedy licensing bodies, and it is because the profession is determined to see an end to this traffic that it is equally determined upon a rebuilding of the General Medical Council, for it well knows that any scheme of improvement, however good in principle, perfect in detail, and well intentioned, must fail if its execution be entrusted to a body which—by twenty years of experience—we know to be neither willing nor competent to work such a scheme.

Let the claims of the profession not be misunderstood. We ask for an organisation as will ensure that no person shall legally practise medicine or surgery unless he possesses such competency as is necessary for the public safety, and unless he has an education suitable for a gentleman's profession, and we ask that the organisation necessary to ensure these objects shall be confided to those who are willing to use it. Less than this cannot be accepted, and, if Parliament refuses to us at present an executive willing to carry out this reform, it is far better for us to wait a little, and persevere in our efforts rather than consent to an arrangement which would tie the hands of reformers for the next twenty years.

The proposals for reconstruction contained in the Bill of the British Medical Association, and in that of Dr. Lush are, as we have said, the same in principle, but different in detail. The former Bill—Mr. Mills's—leaves the Medical Council as it is, making no change therein save that it groups the University of Edinburgh with that of St. Andrew's, and Glasgow with Aberdeen, the existing grouping being Edinburgh with Aberdeen, and Glasgow with St. Andrew's. To the present Council Mr. Mills would simply add six direct representatives—four for England, and one each for Scotland and Ireland. Thus the complete Council, under his proposition would number thirty persons, of whom six (or one-fifth) would be direct representatives; another six would be Crown nominees, one other member would be the President, and the remaining seventeen would be the representatives of licensing bodies.

The proposal of the Bill of the Medical Alliance Association, introduced by Dr. Lush, is essentially different from this. That Bill seeks to add *four* direct representatives, but at the same time to reduce the number of the Council. For these representatives it makes room by disfranchising the Apothecaries' Companies of London and Dublin, and the Glasgow Faculty of Physicians; and it reduces the number of councillors by proposing to appoint only four Crown nominees, and to make one of them President instead of electing one additional member to that office. It furthermore proposes to group the University of Durham with those of Oxford and Cambridge, the Dublin University with the Queen's, and the Scotch Universities in one group. Thus the Council proposed by Dr. Lush would consist of nineteen persons—or five less than at present—four of them being Crown nominees, four direct representatives, and eleven representatives of licensing bodies.

Of these two propositions there can be no doubt that that of Dr. Lush is much preferable—we might almost say it is the only practicable suggestion. In the first place it meets boldly and honestly the faults of the present constitution of the Council, which faults Mr. Mills's Bill connives at, though we fully believe that the promoters of that measure are fully conscious of them. We quite believe that if the Medical Reform Committee of the British Medical Association were asked whether they thought that the two Apothecaries' Companies—the Durham University and the Glasgow Faculty—were fairly entitled to a voice in the General Medical Council, it would be admitted that they do not. We think it a doubtful policy on the part of an Association which represents the general practitioners to buy off the insignificant opposition of these bodies by tolerating a serious error in the constitution of the Medical

Council, and we therefore prefer the proposals of Dr. Lush, which, if less diplomatic, are certainly more honest.

But the great objection to Mr. Mills's Bill—and it is one which the Medical Council party have not been slow to use for the purpose of their opposition to any measure of reform —is that it adds one-fourth to an already unwieldy council, and thereby at once increases its cost and diminishes its chance of proving a good working body. It is the opprobrium of the General Medical Council that it is characterised by little else than endless verbosity, and that there exists within it such a diversity of conflicting interests and so little cohesion of any one party, that its meetings show little sign of a definite policy on any point, and result in little else than vague recommendation, or colourless resolutions. It is a reasonable objection to an increase in the talking power of the Council, that the probable effect would be a decrease in administrative power, and for this, if for no other reason, it seems to us that Dr. Lush's proposal is more sensible and more effectual than that of Mr. Mills.

But there is a more practical yet equally forcible objection to the method of reconstruction put forward by the British Medical Association, and that is that there are really no funds for the payment of six additional Councillors.

The following table will illustrate this :—

*Comparative Income and Expenditure of the General and Branch Councils during the last seven years.*

| | 1872. | 1873. | 1874. | 1875. | 1876. | 1877. | 1878. |
|---|---|---|---|---|---|---|---|
| | £ | £ | £ | £ | £ | £ | £ |
| Income ... | 6106 | 5338 | 6004 | 5877 | 6286 | 6035 | 6206 |
| Expenditure | 3446 | 5215 | 6882 | 6698 | 5911 | 6684 | 6322 |
| Excess of Income ... | 2660 | 212 | — | — | 374 | — | — |
| Excess of Expenditure ... | — | — | 878 | 820 | — | 649 | 116 |

Average for seven years of Income, £5979
" " Expenditure, £5867

It will be seen that—with the exception of one year—the Council has for the last five years been drawing steadily upon its capital, and that in that period it has reduced its money balances by £2,089, although during that period there was no decadence, but rather a steady increase in its income. Of the six thousand a year expended by the Council, nearly one-half (£2,893) went during the last recorded year on fees to Councillors. This seems a very large sum, but considering the number of the members and the length of the sitting, it is not so.

The remuneration to a member of the General Medical Council, including his travelling and hotel repayments, and his attendance at Branch Councils—judged from the expenditure of the year 1878—is, on an average, per annum, as follows—

1. For a member resident in London ; about £80.
2. For a member resident at a distance, including all his expenses ; about £160.
3. For a member of the Executive Committee, resident in London ; additional, about £30.
4. For the same, resident at a distance ; from £60 to £130.

We are aware that it has been proposed to reduce the remuneration of Councillors in order to bring the expenditure of the Council within its means ; but while we are anxious for economy of administration, we emphatically demur to such a proposal. For members resident in London, who can pursue their profession and receive their fees during the sittings of the Council, there might be no great hardship in asking them to attend its meetings gratuitously, but for members who have to travel from Scotland, Ireland, or from distant provinces, to pay first class travelling and hotel expenses, and to sacrifice their practice earnings for a fortnight's absence from home, perhaps twice each year, it seems to us that £160 is all too little.

It would, we think, be subject for regret if membership of the Council came to be sought for as an office of emolument, but we think that there is no danger of such contingency at the present rate of payment, while, on the other hand, it seems clear that to curtail the fees would be to make it impossible for practitioners in the full swing of their profession to accept office, and would thus tend to throw the representation into the hands of retired doctor-princes, of whom, we submit, we have already too many, or of needy practitioners whose experience of medical education and practice is narrow.

The six direct representatives proposed by Mr. Mills, would cost the profession about £1,000 a-year, and we know of no feasible way of providing that sum except by removing six other representatives who have no claim to the seats or the emoluments, and this is exactly what Dr. Lush proposes.

As to the means by which the medical profession at large is to choose its direct representatives the two Bills agree.

The proposed machinery is as follows:—When an election is to be held the registrar of each branch council (who is sworn to hold a fair election) will publish in the medical and other journals a notice fixing the time and place of election, and will for a month from date of such notice receive nominations of any person "qualified as a registered medical practitioner, to represent the medical practitioners in that part of the United Kingdom." Within that month any twelve registered medical practitioners may, in proper form, nominate such person. If the nominations do not exceed the vacancies, then the nominee will be declared *ipso facto* elected. If the nominations exceed the vacancies, then the branch registrar shall forward by post to each registered practitioner within his division of the kingdom a voting paper, which the recipient shall, in the presence of a witness, initial opposite the name of the candidate whom he selects, and then return to the registrar, who shall next day count the votes, reject the invalid papers, and report the result to the General Medical Council. Representatives so elected shall hold office for five years.

We may, we think, disregard any objection made to "direct representation" on the ground of the impracticability of this system, for it is perfectly simple and inexpensive, and not seriously open to abuse or fraud. It is our calculation that such an election held every five years, and assuming it to be always a contest, would cost the Council at most £200, and that outlay would be well repaid—if in no other way—by the opportunity which it would afford for a thorough revision, each five years, of the names and addresses in the Medical Register.

Upon the general question of the advisability of admitting to the General Medical Council a class of members who shall be elected by the profession at large, we shall not enter into controversy. We have said enough to prove that—for want of such representatives—the Medical Council has allowed many questions of vital interest, both to the medical profession and to the public, to lapse from its memory. If we are told that "direct representation" would introduce "agitators" to the Council, we reply that the stimulus of a few representatives independent of the interests of Colleges and *en rapport* with the interests of the profession has long been needed, and would be of great advantage to the Council, and if it pleases any one to call them "agitators," the name will be no opprobrium in a conclave in which agitation is the one thing needful.

◆

## THE LUNACY LAW AMENDMENT ACT.

But one opinion of Mr. Dillwyn's Lunacy Law Amendment will be formed by competent critics, and that will be that it is a very impotent and pernicious measure, which might be more fitly designated the Lunacy Law Confusion Act. It is certainly disappointing to find that after years of cogitation, and an inquiry which must have been very costly to the country, Mr. Dillwyn has nothing better to offer us than this Bill, which, if it became law, would unsettle much that is excellent in our present system, introduce some dangerous novelties, and set up some fictitious safeguards of personal liberty in place of the tolerably substantial ones which we now possess. The Bill does not grapple with the real difficulties of lunacy legislation, it marks no advance in our treatment of the insane, and contains scarcely a single provision that has not been again and again discussed and discarded by practical men. With timid halting step it enters upon some promising tracks merely to start back again, as if frightened at its own temerity, and with stolid effrontery it carries through some eminently silly proposals. It would be flattery to apply Horace's most familiar metaphor to Mr. Dillwyn and his Bill. Were we inclined to adopt a modification of the figure we should speak of a labouring mole and the birth of a preposterous rubbish heap.

Anxious to do full justice to the Bill, and to give prominence to any good things that it contains, we have searched it in the first place for proposals which we could approve and recommend. Unfortunately these are few in number, being limited to the provisions of the 9th and 14th sections. By the first of these it is provided that the Chairman of the Board of Commissioners in Lunacy shall, henceforth, receive such salary as may be fixed by the Lord Chancellor with the consent of the Treasury; that one of the Commissioners shall be appointed as Deputy Chairman, and receive a certain payment in respect of that office beyond his stipend as a Commissioner; and that two additional Commissioners, one a barrister and the other a medical man, shall be appointed, which would bring up the number of paid commissioners to eight. By the latter section referred to, that is to say the 14th, it is provided that public asylums which have hitherto been visited only once a year by the Commissioners shall in future receive two visits annually.

Now it is obvious that the payment of the Chairman of the Commissioners is not only an act of justice but of necessity, for that labourious office must be filled by a man of exalted rank and ability if the authority of the Board is to be maintained and its policy vindicated, and no one possessing the necessary qualifications, would be likely to accept so thankless a post, without the inducement of a large salary. It is not to be expected that we shall again meet with the philanthropic ardour which has sustained Lord Shaftesbury through a life-long drudgery on behalf of the insane, and we must therefore be prepared to purchase at its full market value the official capacity and industry required in the Chairman of the Board of Commissioners, combined of course with that zeal in the public service and those benevolent dispositions which are not to be bought, but which are rarely wanting in English statesmen. The Chairmen of the Local Government Board, of the Committee of Council on Education, of the Prison Commission, the Ecclesiastical Commission, and the Civil Service Commission, are all paid, and no good reason can be adduced why the Chairman of the Lunacy Commission should not be paid also. Lord Shaftesbury certainly has done the work for thirty-five years for no reward but the approval of his own conscience, and the gratitude of his fellow-countrymen; but that creates no ground for hoping that anyone else will exhibit similar disinterestedness, especially when it is borne in mind that the public gratitude, which we have alluded to as part of Lord Shaftesbury's recompense for his services, has been mixed of late with a good deal of public grumbling against the system which he has done so much to elaborate, and the Board which he has formed and moulded. We suspect the public do not really know how large a share of the work of the Commissioners in Lunacy has been borne by Lord Shaftesbury. Had they have been aware that he has not only been the presiding spirit at the Board, but that he has been a working Commissioner attending the office almost daily, visiting asylums from time to time, and keeping up a detailed knowledge of institutions, men, and cases like any of his paid colleagues, they would not, we think, have listened with patience to the aspersions which have been cast upon the work of the Commissioners by social fanatics and prematurely discharged lunatics. For forty years Lord Shaftesbury has assiduously, punctually, and gratuitously performed a round of public duty which in any other department of the State would have been requited by a salary of £3,000 a year, and which will certainly have to be paid for at that rate in future.

The appointment of a Deputy Chairman to preside at meetings in the absence of the chairman, and to undertake other special duties, would open up a vista of promotion before the Commissioners, and offer an occasional opportunity of rewarding such of them as might have distinguished themselves in the discharge of their ordinary functions. The suggestion is good on the whole, but we should have preferred a proposal to appoint a paid Parliamentary Secretary to the Commission, and to raise the salaries of the Commissioners after a certain length of service. A Parliamentary Secretary, holding a position and salary similar to that of the Parliamentary Secretary to the Local Government Board, would connect the Commission with the Government of the day, and bring it into immediate relations with the House of Commons. The isolation of the Commission has been its weakness in the past; it would have been lost sight of altogether, but for Lord Shaftesbury, and it is desirable that it should in future, like other great public departments, have a representative in the House of Commons who could answer questions, relieving the Home Secretary of that duty, take charge of lunacy legislation when it is deemed necessary, and bring the opinion of Parliament to bear directly on the Commission on all questions cognate to its work, while taking part in its deliberations. Then the Commissioners were either over-paid in the first instance, or are under-paid now, and the latter alternative is the one we are inclined to accept. Their salaries remain where they were when the Commission was first formed, whereas those of most civil servants of like rank have been increased in the meantime. No one will maintain that £1,500 a year is now equal in purchasing power to what it was five-and-thirty years ago. The high respect in which the first Commissioners were held, and the weight that attached to their recommendations, ought perhaps to be in some measure attributed to the comparatively high salaries which they then received, which marked them out as valued servants of the State. Unless the salaries of the Commissioners be raised it is to be feared that their authority will dwindle, and that on the occurrence of vacancies amongst them their ranks will have to be recruited from men of very inferior position to that from which Commissioners have hitherto been drawn. Several superintendents of pauper asylums are at present better paid than the Commissioners who have supervision over them, and who are, of course, compelled to keep up appearances suitable to their supposed high status. The salaries of medical superintendents are increasing all over England, and in a short time the position of affairs will be this—that the best of these medical superintendents will decline to accept commissionerships when offered to them, and we shall have second-class men promoted to inspectorial functions, with the result of destroying the repute and usefulness of the Commission. The salaries of the Commissioners ought to be raised to £1,800 at the end of five years' service, and to £2,000 at the end of ten years, if it is wished that they should preserve the dignified position, powerful for the public good, which they have hitherto occupied.

The visitation of public asylums twice instead of once a-year would doubtless be a salutary measure, as under existing arrangements, large numbers of lunatics must pass through these asylums without ever seeing a Commissioner, or having any opportunity of making their complaints in the proper quarter, and it is possible that nearly two years may elapse between the official inspections of a particular asylum. Experience shows that public asylums require to be kept up to the mark as well as private ones, and two yearly visitations are not certainly too much for them. It would be impossible, however, for these visitations to be carried out by the present staff of Commissioners, and if they are to be made statutory two more Commissioners, at least, must be appointed. Mr. Dillwyn may be congratulated on having avoided the tempting but objectionable expedient of appointing Deputy-Commissioners.

Turning from those parts of Mr. Dillwyn's Bill with which we can express some agreement, to the ampler regions where we differ from him, we come first on his proposal to enable justices of counties and boroughs to provide accommodation for private patients by building new public asylums or purchasing existing private ones out of moneys obtained by means of a county rate, or on mortgage of the rates. Now it may or may not be advisable to provide public asylums for patients of the better classes, who are now boarded in private asylums—we waive that question for the present—but it is certainly not advisable nor permissible to provide such asylums at the public expense, and we cannot comprehend how an advanced Liberal, like, Mr. Dillwyn should countenance such a scheme. The rate-payers have quite enough of taxation to support at present without adding to their burdens the cost of erecting luxurious hospitals for nervous invalids of the upper classes. True, it is provided that when a surplus is found to exist in any lunacy district, after payment of all expenses, the said surplus shall be applied to lessening the rates levied for the maintenance of pauper lunatics in the district, which would be an indirect way of compensating the ratepayers for their outlay in the new public asylums, but the existence of a surplus in any district would be exceedingly problematical, for the new asylums could not be conducted in a rigidly economical manner, and would have to receive many patients at unremunerative rates of board. But the principle of applying the rates to the purpose of building or purchasing lunatic hospitals for the well-to-do classes is radically unsound and indefensible. As well might we propose to draw upon the public purse in order to establish infirmaries for them when labouring under infectious diseases, or sanatoria at Ventnor and Bournemouth to which they might resort when suffering from consumption. Insanity is simply a disease involving certain disabilities and limitations of personal liberty, and requiring, therefore to be brought under stringent supervision by the State, but creating of itself no claim upon the public bounty. Lunatics of the better classes should be wholly maintained out of their own funds or those of relatives upon whom they have any legal claim; and not only so, but the expenses of the supervision and protection which the State confers upon them should be defrayed from the same sources. This is so in the case of Chancery lunatics, who not only pay their own maintenance, but are charged a small percentage which covers the whole cost of the offices of the Masters and Visitors in lunacy, and we fail to see why other affluent lunatics who are not in Chancery should be exempt from a similar impost, which would in part defray the expenses of the Commissioners in Lunacy. The rate-payers generally might very properly object to supply skilled inspection to wealthy lunatics who can well afford to pay for the benefits which such inspection confers; and the ratepayers would be themselves demented if they did not object to advance money, with a very shadowy prospect of repayment, in order that the whim of having all lunatics in public asylums, may be at once gratified.

There are really three classes of lunatics to be dealt with in this country, not two, as many writers and talkers on lunacy suppose. There are pauper lunatics who are and must be provided for out of the rates; there are indigent lunatics, who can just afford to pay for a bare subsistence, and who might properly receive charitable aid, in an undemoralising way, by having hospitals built for them by the benevolent; and there are affluent lunatics, who are able to pay all expenses connected with their illness, including asylum buildings, maintenance, medical treatment, and official inspection. The paupers are already well provided for. The indigents are partially provided for in institutions like Bethlem, St. Luke's, St. Andrew's Hospital, Northampton, and the Coppice at Nottingham, but one of the pressing wants of our day is increased accommodation for this class of the insane; and the affluents are fully provided for in private asylums, registered lunatic hospitals, and their own homes. Of the paupers Mr. Dillwyn takes no notice; about the indigents he manifests no solicitude; for the affluent he seeks to build palatial retreats out of the rates. The ratepayers, we suspect, will button up their pockets, and decline to contribute to such an undertaking, even although by doing so they could have the satisfaction of knowing that private asylums are abolished, and that the State has made another encroachment on private enterprise, and become an asylum proprietor. The next step of grandmotherly legislation will be for the State to buy up all druggists' shops at three years' purchase, so that we may have our medicine free from adulteration, and that chemical adventurers may no longer make exorbitant profits out of our diseases.

Should it have been determined after calm and full deliberation that it is expedient for the State, even now, and when public feeling is not wholly prepared for such a step, to take over the care of all the insane of every class, we can conceive a well-digested and equitable scheme by which the necessary lands, buildings, and furniture might be at once obtained, money being advanced by the Public Loan Commissioners at a remunerative rate of interest, to be repaid by instalments in a term of years; but Mr. Dillwyn's scheme is not, we think, equitable or well digested, and its money clauses are simply indefensible. Then not only is the scheme ill-digested and inequitable, but it would be inoperative, for the powers conferred upon the justices of counties and boroughs to provide asylums are purely permissive. Does anyone believe that any bench of justices would take action under Mr. Dillwyn's Bill? Mr. Dillwyn apparently does not believe it himself, for in one instance in the metropolitan district he makes it incumbent on the justices to provide one of his new modern asylums within a period of three years. Is it that, full of misgivings about his own plan, he desires one little preliminary experiment to be made in it? How else are we to account for this unique idea of compelling the metropolis to do what all the rest of the country is left to do or not to do as it pleases?

*(To be continued.)*

## PUNITIVE TREATMENT AT HIGH SCHOOLS.

A PHYSICIAN who was called upon lately to attend a girl suffering from severe bronchitis, found that a slight catarrh had been converted into the graver disease by the persistent attendance of his patient at a London high school at which she is a pupil during cold foggy weather, in spite of the warnings and solicitations of her parents. Her obstinacy in going out of doors when she ought to have remained in her own room, was caused, it appeared, not by any innate love of school-work, but by an ambitious desire to retain the high position in her class to which she had, with much labour attained, and which would have been sacrificed by any temporary absence. Of an intensely nervous temperament, this delicate girl shrank from the idea of going down in her own little world, and so went on exposing herself to inclement weather and alternations of temperature when she ought to have been snug in bed, and working her brain when her feverish condition demanded complete rest. And not only so, but throughout her illness the knowledge that by the rule of the school—which we venture to think a very bad one—she would on her return have to go to the bottom of her class and struggle upwards once more, handicapped by the loss of all the tuition that had gone on in her absence, distressed and worried her to such an extent as to constitute a complication of her illness and retard her recovery. During her convalescence, too, the same painful anticipations haunted her, and made her impatient under the medical restraints imposed on her, and eager to begin again a course of study to which her strength was not equal.

In Erewhon diseases were punished and criminals submitted to medical treatment, and it would seem that some English high schools for girls have taken a leaf out of the Erewhon code, and provided punitive measures against sickness, for it is, of course, a punishment to a proud and sensitive girl to be sent to the bottom of her class. A temporary absence from school on account of sickness entails inevitable disadvantages, and it strikes us as being unfair that to these should be added gratuiously a deprivation of the "energy of position" in the class. Surely some method might be devised by which a girl might resume on her return from sick leave, and without any injustice to her companions, either the place which she held when she broke down, or her average place for the previous part of the term. The system to which we have referred of degrading girls who have been invalided is certainly objectionable and dangerous from a medical point of view. It is apt to lead, in the case o diligent and aspiring girls, to the concealment of illness, and undue postponement of treatment, and it is not unlikely to add a new element of danger to the ailments of those who are of fine and fragile organisation. We do not know how far the practice extends, or whether, indeed, it exists in more than one London high school, but wherever it has been introduced it ought to be amended without delay.

Competition as an instrument of education must be used with extreme caution in the case of girls. If it becomes a goad to stimulate exhausted, jaded, or overstrained powers, it will work incalculable mischief. Only in moderation, and under strictly equitable arrangements, should its use be permitted in girls' schools.

AMONG the newly-elected members of the Royal Institution of Great Britain and Ireland occur the names of Drs. Crichton Browne and Mansell MacCullock

# Notes on Current Topics.

## The Dangers of Smoking.

It has on frequent occasions been contended that the enjoyment of a cigar carries with it a certain amount of danger to the smoker, cases being cited to prove the possibility of syphilitic inoculation through such a source. However rare such occurrences may be, it cannot be gainsaid that they do sometimes arise; that occasionally a specific ulcer is contracted on the lip followed by secondary eruptions, and every indication of syphilitic infection, in patients who can only be supposed to have come accidentally by the disease. A case in point is quoted in a recent number of the *Archives of Dermatology*. A physician had charge of a patient in a stage of advanced chancre, and received from him complimentary presents of valuable cigars he being the son of a manufacturer. Smoking the cigars by the physician was followed by ulceration of a persistent fissure which had existed on his lower lip many years. This eventually developed into a true chancre, and the constitutional symptoms only yielded after considerable treatment. The possibility of such a mode of infection is far too little considered. The makers of cigars are notoriously dirty and diseased, and nothing is more likely than that they should transfer the infection to the tobacco they manipulate. Given this virus-charged leaf, and an excoriated lip, and all the elements necessary to complete syphilisation are present. The danger is a common one, and ever present. How to avoid it should be the study of each smoker. Possibly the wisest plan to pursue is to smoke always through a cigar-holder or tube.

## St. John Ambulance Association.

This useful association is making steady progress, and branches are being formed almost weekly. In our last we drew attention to the great success attained by the Blackheath centre; another was very recently formed at Blandford, and now one has just been started at Bournemouth, where a very representative and influential local committee has been formed. The medical profession have everywhere recognised the value of the work done under the auspices of the Association, and at Bournemouth we find that several of the leading medical men of the town are on the committee. Lectures are intended to be given to the volunteers, the police, the railway *employés*, &c. We wish the movement every success, and should be glad to see a centre established in every town of any size in the kingdom.

## Heredity.

Dr. Kempster in his able report on the Wisconsin Northern Hospital for the Insane, gives a remarkable history of the family of one of his patients illustrating the operation of the intense taint which results from tendencies to nervous diseases in both parents. The father was eccentric; the mother died insane; the eldest child, a son, became insane and shot himself; the second child, the eldest daughter, is now in a lunatic hospital, the second daughter is insane and an inmate of another lunatic hospital, another daughter became insane and committed suicide by taking poison, another son was insane and shot himself, another daughter became insane and hanged herself; the eldest child of the eldest daughter above-mentioned has already become insane; thus making a beginning of the evil in a second generation.

## Dr. Farr.

The government recognition of Dr. Farr's invaluable services is to be fittingly followed by a testimonial to be subscribed chiefly by the profession of which Dr. Farr is a member. The committee to carry out the idea is one of the most influential that has ever been brought together, and includes the most prominent heads of the medical profession, as well as several noblemen and gentlemen interested in the question of hygienic reform. Mr. R. B. Martin, of 68 Lombard Street, is the honorary treasurer.

## Friedrichshall Water.

This is one of the most useful saline purgatives that we possess, producing activity in all the digestive functions, and thus eliminating matters otherwise to be thrown off as uric acid by the kidneys. The water itself as bottled at the spring in Germany and exported to this country, is far more efficacious than the salt obtained by evaporation, but few of those who are in the habit of taking the water adopt the proper method of administration. About seven ounces is an ordinary dose, and it should be taken an hour before breakfast, followed by a cup of hot tea or coffee, when a free action of the bowels is usually the result. Sir Henry Thompson in a lecture upon the natural mineral waters says that Friedrichshall water when administered for derangement of digestion with loss of appetite and foul tongue, should be given every morning before breakfast combined with hot water, and diminishing the quantity by a little every day or every few days. He adds that one of the characteristics of this water is, that the longer it is taken the smaller is the quantity necessary to effect the purpose. If, for example, seven ounces of the water be sufficient for the purpose required on the first day of its administration, six ounces will act equally as well on the second day, and five ounces on the following.

## Provident Dispensaries.

A provisional committee of gentlemen interested in a movement for depauperising the dependent classes, is engaged in making arrangements to hold an early public meeting to consider the details of a proposed scheme to this effect. The attempt that is to be made deserves the attention of the profession, and especially of the governing committees of large hospital charities. It is undoubtedly true that the resources of such institutions are unduly strained at present to meet the necessities of an immense number of sick poor who, unable to pay the ordinary fee for professional attendance, would yet gladly avail themselves of any means whereby they might receive advice on terms not entirely gratuitous. The provident dispensary scheme is an admirable method of meeting the wants of this great class. By it the advantages of skilled treatment will be afforded at all times in return for a definite annual contribution per head or per family; and under the direction of a committee with whom no considerations save those of general benefit will have weight the administration of the business of the association will be freed of all the objectionable characteristics that have served to mark private ventures of the kind with opprobrium. The "Metropolitan Provident Medical Association," as the new society will be called, is a much-required step in the direction of reform. We shall return to the question at greater length in an early issue.

## The Coroner's Court.

A CASE illustrating the advisability ot having skilled pathologists attached to the Coroner's Court occurred last week in Clerkenwell. An inquest was held on a child ten weeks old, in consequence of a practitioner's certificate that death occurred from wasting and neglect. The mother of the child was in the habit of going out daily to work, and during her absence it was left at the nursery conducted by the sisterhood attached to St. Alban's, Holborn. The medical man considered that the mother had neglected her child by not suckling it, and he also thought the condensed milk given as food most deleterious. The certificate reflected most seriously upon the mother, and if substantiated might have resulted in a charge of manslaughter, and would of necessity have implicated also the sisterhood of St. Alban's. The mother, however, suggested a countercharge against the medical attendant, implying that the child had not been properly treated. Under these circumstances Dr. Hardwicke issued his order for a post-mortem examination to be made by an independent witness, and adjourned the inquiry for his evidence. The examination was made by an official from the Hospital for Sick Children, who evidenced that the child had died from a very rare but well-recognised disease named sclerema, which invariably proved fatal to infants. On this evidence the jury returned a verdict of death from natural causes, no blame being attached to any one concerned.

## Herpes of the Larynx.

BEREGSZASZY reports in the *Genæskund Cour. der Nederl* three cases of phlyctinular inflammation of the vocal cords. Laryngoscopic examination revealed the presence of small vesicles surrounded by a red zone: these vesicles transformed into pustules and were cured in a few days without any medicine. In one case there was at the same time a herpes of the pharynx: the affection had been considered as diphtheritic in its nature, but laryngoscopic examination (the patient had hoarseness at the same time) clearly revealed the nature of the affection; on the epiglottis and especially at its free border, on the ventricular bands of the larynx and on the ary-epiglottic folds, there were small characteristic vesicles of the nature of which there could be no doubt.

## Local Temperature in Phthisis.

M. LEPINE recently read a note before the Paris Société de Biologie on local temperatures in phthisis. In a number of patients with cavities in the lungs he had ascertained that there was no difference of temperature between the region of the thorax corresponding to the cavity, and the axilla or arm of the same side. Thus in one patient the thermometer showed 39·6 deg. in the thorax, and 39·6 deg. in the inner surface of the arm. To sum up, according to M. Lepine, cutaneous hyperæmia in phthisical patients may exist equally in the brachial and thoracic regions.

## Acuteness of Vision and Perception of Colours in Uncivilised Nations.

DR. COHN, in a contribution to the *Centralblatt fur praktische Ohrenheilkunde* for 1879, states that he examined the visual powers of eleven Nubians, and found the acuteness of vision twice as great in them as in the healthy eyes of Europeans. Only their chief and priest, who had studied Arabic for nine years and had read much, was myopic. The perception of colours in the Nubians was found to be excellent. As Virchow has already observed, they are deficient in verbal expressions for different colours, there being no distinctive words for green and blue. Experiments with coloured wools, however, showed the incorrectness of the opinions of Geiger, Gladstone, and Magnus, that the linguistic deficiency indicates a defect of vision for colours. Virchow also found, on examination of some Lapps who were in Berlin, that their vocabulary does not enable them to express the differences in colour which they perceive, although their sense of colour is well developed. In connection with this a remarkable fact was observed. While all the Lapps used the same word —*aliicht*—for blue, and had no hesitation in selecting the colour, the Nubians had the greatest difficulty with this colour. Even green was distinguished by the Lapps pretty accurately, though with less certainty. The coloured ribbons, also, which the Lapp women wore, indicated the acuteness of their perception of colours. According to Dr. Almqvist, the Tschukschès of the East Cape in Siberia have a well developed perception of colour. Among the Georgians of the Caucasus in the Russian army, Reich found the acuteness of vision to be higher than normal in 83·5 per cent.; in 32·1 per cent. it was double, and in 3·5 per cent. more than double the normal average.

## Alteration of the Maxillary Bones in Ataxy.

AT a recent meeting of the Société Médicale des Hopitaux of Paris M. Vallin stated that he had observed, during the course of locomotor ataxy in several patients, a loss of the teeth which takes place without caries or pain. An osseous atrophy of the alveolar border occurs, on account of which the tooth drops spontaneously out of its socket. There is thus a trophic alteration of the maxillæ, not previously described, which moreover merits attention, since it may be an early phenomenon of the disease. The communication of M. Vallin was confirmed by some cases related by MM. Luys and Tereboullet.

## Doctors in the Society Papers.

THE morbid curiosity for petty details of purely personal and private matters which the so-called "society" journals have carefully fostered and now live by gratifying, is extending its unpleasant inquisitiveness into the ranks of our own profession. Consequently many of our *confrères* find themselves (no doubt much to their annoyance) continually being gratuitously advertised in these weekly depositories of small scandal and trivial tittle-tattle.

The latest instance of this is seen in Saturday's *Whitehall Review*, apropos of the awfully sudden and lamented death of Dr. Fairbank. The *Whitehall* Paul Pry must needs parade before the public a wholly unnecessary account of a dinner party at which Dr. Fairbank was present the evening before his lamented decease, and because thirteen happened to sit at the table must needs, with at least questionable taste, refer to the old woman's superstition respecting the ill-luck of a party consisting of that number of persons. At any rate it seems quite gratuitous to introduce the names of the host and of the guests of the party. The host's name is given as "Dr." Zacharie, but we fail to discover this name in the Medical Directory. There is a gentleman of that name called in the Post Office Directory an Orthopædist, and there was, we believe, a book on corns or something of that kind recently published written by J. Zacharie. But this can scarcely have been the host who entertained such well-known professional gentlemen as Dr. Fairbank, Dr. Morell-Mackenzie, Dr. Alfred Meadows, and Mr. Alfred Cooper. Even if such were the case we fail to see why the fact should be trumpeted forth to the world through the press. We notice, however, that "Dr." Zacharie's address is carefully recorded. Is it possible the eminent "orthopædist" is in want of an advertisement, and secures it cheaply by asking an editor to dine with him?

### Military Sinecures in Cyprus.

A CORRESPONDENT of a Dublin contemporary calls attention to the imposition upon army medical officers at Cyprus of civil duties not within their department at all. It appears that each district in Cyprus is given a medical officer, who, for the munificent sum of 6s. 6d. a day is to attend on the police, take medical charge of the jails and of the dispensaries for the poor, to perform all difficult surgical operations, pay particular attention to ophthalmic cases, serve as medical jurists, act as sanitary advisers and inspectors of nuisances, together with employing their leisure time in watching the progress of epidemics. Of course, under the circumstances civil officers have not presented themselves in sufficient numbers, and military medical officers have been ordered to assume the functions.

### The last Legal Refuge of the Anti-Vaccinators.

In the London Court of Queen's Bench last week a singular objection was raised to the conviction of persons for not having their children vaccinated, viz., that vaccination itself produces small-pox, and is therefore illegal and contrary to the Act. Mr. Tomlinson appeared on behalf of a person who had been convicted under Section 31 of the Vaccination Act, and he objected that the conviction was bad, as being contrary to the next Section (32), which sets forth that any person who shall wilfully communicate small-pox shall be deemed to commit an offence. Mr. Justice Lush inquired if it was really meant to be shown that vaccination is a communication of the disease called small-pox; and on being told that this was what was contended the Judge remarked that the Court really could not listen to such on objection; and the application was rejected accordingly.

### Indian Medical Service.

NOTICE has been given that an examination of candidates for twenty-five appointments as Surgeon in Her Majesty's Indian Medical Service will be held in London in August, 1880. We ask the attention of those who think of competing to the new Indian Medical Warrant, which appears in another part of our issue.

A correspondent of the *Irish Times* writes as follows:—

"Prior to the issue of the late Army Medical Warrant the Indian Medical Service was very popular; but by the recent orders several of the best appointments in each presidency will be abolished after the 31st March next, and the surgeon-generals for the heads of the departments will be selected from the Army Medical Department. The young officers of the Indian Service are thus precluded from the hope of ever rising to be the heads of the department, and not more than 5 per cent. can reasonably hope to rise higher than the grade of surgeon-major.

"The Indian Service is also debarred from the increased pensions granted by the warrant to officers serving at home, and as every member must retire at the age of 55 unless he has attained a higher rank than that of surgeon-major, the prospects are very miserable, more especially as the pensions in the lower grades are wretchedly small. The Indian Medical is not an effete service, for it is well known the best men from the different medical schools have entered it, and it is amazing that Government, in the guise of reform, should ruin the prospects and inflict a grievous insult on a very important branch of its service.

"The day has gone by when India will any longer attract picked men, and the sooner the present state of affairs is made known in every medical school in Great Britain the better."

### A New Method of Acquiring Diplomas.

A SYSTEM of fraud has lately been discovered in the Medical Faculty of the University of Naples. Its registers being open to public inspection, presumably without any supervision, an ingenious scamp hit upon the scheme of making clandestine entries, and obtaining official certificates from the authorities who did not detect the interpolations. For these certificates he obtained sums of money from various persons, some of whom have practised and actually received parochial appointments on the strength of them. One of the latter, who in 1870 underwent twelve months' imprisonment for deserting from the army, has already been arrested as an accomplice. Diplomas have also been forged, and some of these go back two years.

### Help for the Widows of Medical Men in France.

THE *Union Médicale* says that a great number of medical practitioners have petitioned the Legislature to sanction the bestowal of pensions on the widows and orphans of practitioners who have lost their lives while pursuing their calling amidst infectious and epidemic disease. M. Talandier, in the name of the Committee of

Petitions of the Chamber of Deputies, reports highly in its favour, declaring that "Every profession is, for those who pursue it, a field of battle; and every profession is also, for those who bring to it the austere sentiment of duty and the heroic spirit of devotion and sacrifice, a field of honour." He does not think the argument that the members of these professions enter them voluntarily, while the soldier is forced to expose his life to risk, is worth consideration; and terminates his report by recommending that the petition should be immediately brought under the notice of the Ministers of the Interior and of Public Instruction. This was at once agreed to.

---

## A Therapeutic Note—Tartrate of Morphia.

The new preparation of neutral tartrate of morphia is a useful adjunct to our therapeutics. Being very soluble it passes quickly out of the system, and gives less of the unpleasant after effects than either the muriate or acetate. Its great solubility makes it particularly advantageous for subcutaneous injection. It gives little smarting or irritation when thus administered, and the solution never clogs the finest needles.

---

Dr. Von Schmidt, the notorious cancer-curer, whose doings in London some time since we had the satisfaction of exposing, and who soon after migrated to Paris, is now in the hands of the police authorities of that city for illegal practice.

---

The Belgian Royal Society of Public Medicine is organising, in connection with this year's independence *fêtes*, a General Congress of Public Hygiene and Medicine, to be held in Brussels at the Palace of the Academies next August.

---

Of the 33 sufferers from the fearful explosion at the Glasgow Ironworks on Friday night, who were conveyed to the Glasgow Royal Infirmary, 26 have died, and it is feared that the chances of saving two or three of the others are very slight.

---

A fire broke out in the central block of Netley Hospital, Southampton, on Thursday last. A body of seaman and marines were at once landed from the *Hector* guardship, and, with the hospital staff, got the fire under in about an hour. The museum was considerably damaged, more by water than fire.

---

Three medical students were convicted at the Marlborough Street Police Court on Friday last, for committing a breach of the peace at the Criterion Restaurant, and interfering with the police in the discharge of their duty. A cry of "St. Bartholomew's and St. George's to the rescue!" was raised, but fortunately it produced no following, and the three rowdies, unable to drag others into the mire, were housed alone for the night at the public expense, and the next day brought up, reprimanded for their conduct, and fined £5 each. When will medical students look upon this kind of thing as utterly debasing to men who should aspire to be gentlemen?

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Provident Dispensaries and Public Health.—At a meeting of the Glasgow Philosophical Society, held on the 3rd inst., Mr. James Mactear, in the chair, Dr. James Christie, the Medical Officer of Health for Hillhead, read a paper on "Provident Dispensaries and Public Health." Dr. Christie commenced by saying that the establishment of Provident Dispensaries in the metropolis and provinces had, during recent years, excited much attention among social reformers, and the efforts put forth had been at least hopeful. The first combined effort to remedy existing evils was made in March, 1870, exactly ten years ago, and had its origin in the ascertained abuse of metropolitan medical charities, and in facts brought to light through the investigations of the Charity Organisation Society. Provident dispensaries were established for the purpose of getting out of the difficulties of medical charity abuse and of successfully grappling with mendicity. Though having their origin in the rectification of existing evils, the system of having such dispensaries was now being discussed on its own merits, and should be considered as a question of social science in the department of Public Health. Dr. Christie proceeded to consider the question "Is there any necessity for the institution of such dispensaries in the city of Glasgow and in similar large centres of industrial population?" That question he, of course, answered in the affirmative, though the necessity did not in Glasgow arise out of any abuse of our medical charities; nor from any prejudicial interference on the part of our hospital and free dispensary system with the interests of medical practitioners; nor from obstacles from the operations of such medical charities in the suppression of mendicity. He pointed out that of the 38,910 patients treated in connection with the four medical charities in Glasgow, 29,409 were treated in the public dispensaries, and since that time the operations of the Glasgow Medical Mission had been extended and the public dispensary at Anderson's College had been opened. But even although 39,000 patients had been treated, he did not think that the private charities of the city were abused or taken advantage of by the public for the purpose of avoiding payment for which they were able to pay. Indeed, so far as he had been able to observe, there was nothing whatever of a pauperising tendency in the out-door patient department of the hospital dispensaries; and he did not think that there was any ground for complaint, on the part of medical practitioners, as to the free dispensary system, as carried out in Glasgow, interfering with professional interests. In the discussion which followed, Dr. Glaister said that Dr. Christie had given a rosy aspect to the state of medical matters in Glasgow, as his experience went to show that there was a great abuse of medical charity in Glasgow. A provident dispensary was a thing he heartily approved of if they got the co-operation of the classes to whom it was applicable. There were already clubs or societies where the male members of a family could be helped, but the want was for the wives and children. Dr. Lothian, as the result of his experience at the Royal Infirmary, stated that with the exception of a few, there had not been any advantage taken of the dispensary by people able to pay. The Chairman made some remarks as an employer of labour.

Glasgow Science Lectures.—The last of the series of Science Lectures was delivered in the City Hall on the 4th inst., by Mr. George J. Romanes, M.A., F.R.S. Sir William Thomson occupied the chair, and there was a large attendance. The subject of Mr. Romanes' lecture was "Mental Evolution." The subject, he said, was one that was entirely peculiar to the present generation, and was exceedingly comprehensive, running into many more or less abstruse branches. The platform of assumption on which they had to start was that of the truth of the general theory of organic evolution as distinguished from mental evolution, illustrating his views by means of diagrams. Although all competent persons were agreed now as to the truth of the evolution of the species. there was a difference of opinion as to the evolution of mind; that was to say, that while they were willing to allow the process of evolution to all below the human mind, a hard and fast line must there be drawn which science could never get over. There arose, however, an enormous amount of evidence in favour of the view that the human mind, like anything underlying nature, must have been evolved. Therefore the burden of proof lay with those who said it had not been evolved. Professor Mivart allowed that the mind of man and the mind of animals were almost one, with one exception. The power man boasted of was thought, and of thought judgment was the simplest element; so that if the animal could think, man and the brute would be brothers. We knew, the lecturer said, that in the matter of speech vowel sounds were a combination of musical notes, and that there was a species of ape which had a very fine ear for music; and there was nothing easier than to imagine a species of these animals which could utter vowel sounds. Thus we had here the first species of articulation. He thought that Mivart's idea admitted of very easy refutation. If he believed in the evolution of corporal structure, and of the structure of the mind of the lower animals, then the only presumption was that the mind of man was evolved. The lecturer thought that the theory of evolution had nothing to fear. while it had everything to welcome, in the science of Psychology. Some might not like to hear that it was so—to feel that our life was one with the life of the brutes, or that the magnificent structure of the mind had its roots far hidden in the depths of the soul bestial. They might think that the time-honoured distinction was being broken down, and all our most cherished hopes and convictions were being dissipated; but he did not mean to discuss the present tendencies or the future actions of scientific research. In any advance which science had made in the region of traditional belief she had been met with the cry of terror. Yet on looking through the history of science this terror had not been justified, and what had been in the past might also be in the future. Although science had approached nearer than ever to the throne of man's highest hopes, he did not say that she must approach it with a desecrating hand. Professor MacKendrick proposed a vote of thanks, suggesting the judicious compromise between superstition and common sense.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this Society, held in the Faculty Hall on the evening of the 5th March, Dr. Ebenezer Watson read an excellent paper "On the Treatment of Stricture of the Urethra." This is a subject very provocative of warmth of feeling in Glasgow; and the retort courteous is not unfrequently somewhat exceeded. Dr. Watson advocates the old treatment of gradual dilatation; in certain exceptional cases he recommends internal urethrotomy. He entirely disapproves of Holt's method; as Holt's instrument cannot be introduced until a No. 4 catheter can be admitted into the urethra, the cure may then be said to be completed. Professors Macleod and George Buchanan took part in the discussion.

REGISTRAR-GENERAL'S RETURNS.—According to the weekly returns of births, deaths, and marriages, the death-rate in the eight principal towns of Scotland for the week ending with Saturday, the 28th of February, 1880, was 22·1 per 1,000 of estimated population. This rate is 4·5 below that for the corresponding period of last year, and 3·4 below that for the previous week of the present year. The lowest mortality was recorded equally in Glasgow and in Greenock, viz., 21·0 per 1,000; while the highest was in Paisley, viz., 34·0 per 1,000. As formerly stated, there is reason to believe that the population of Paisley is in excess of the estimate, and if such is the case this proportion is too high. The mortality from the seven most familiar zymotic diseases was at the rate of 4·0 per 1,000, or slightly in excess of that for last week. An increase of deaths occurred from whooping-cough, chiefly in Glasgow and Aberdeen. Nine of the deaths which occurred in Dundee were caused by measles. The number of deaths from inflammatory affections of the respiratory organs was 143, or 26 less than the number recorded during the previous week.

## THE NEW INDIAN MEDICAL WARRANT.

THE following Warrant was published in the official Indian *Gazette* on the 3rd of January:—

Under instructions from the Secretary of State for India, the Right Hon. the Governor-General in Council is pleased to direct the following changes in the organisation of the Medical Administrative Staff for the Army in India.

From March 31, 1880, the British Army Medical Department and the Indian Medical Department will form one department for the medical administration of the Army in the three Presidencies.

The establishment for the Bengal Army will consist of—

1 Surgeon-General, Army Medical Department;
1 Secretary to Surgeon-General, Army Medical Department;
1 Secretary to Surgeon-General, Indian Medical Department;
} at Head Quarters.

The statistical duties for the Army, British and Native, will be performed by the Statistical Officer attached to the Sanitary Commissioner with the Government of India.

The eleven circles of medical superintendence will be distributed as follows, each being held by a Deputy Surgeon-General:—

| | | Army Med. Dept. | Ind. Med. Dept. | | | Army Med. Dept. | Ind. Med. Dept. |
|---|---|---|---|---|---|---|---|
| 1. | Allahabad Division | 1 | — | 7. | East Frontier Dis. | — | 1 |
| 2. | Lahore Division ... | — | 1 | 8. | Presidency Dist.... | — | 1 |
| 3. | Meerut Division .. | 1 | — | 9. | Gwalior Division<br>Saugor District | — | 1 |
| 4. | Oudh Division ...<br>Rohilcund District | 1 | — | 10. | Peshawar District | 1 | — |
| 5. | Rawal Pindi Division | 1 | — | 11. | Punjab Frontier Force ... ... ... | — | 1 |
| 6. | Sirhind Division ... | 1 | — | | | | |
| | | 5 | 1 | | | 1 | 4 |

For the Madras Army:—

1 Surgeon-General, Army Medical Department;
Secretary to Surgeon-General Indian Medical Department
} At Head Quarters.

The six circles of medical superintendence will be distributed as follows, each being held by a Deputy Surgeon-General.

| | | Army Med. Dept. | Indian Med. Dept. | | | Army Med. Dept. | Indian Med. Dept. |
|---|---|---|---|---|---|---|---|
| 1. | Centre District...<br>Northern Dist. | 1 | — | 4. | Hy. Subsidiary Force ... ...<br>Hy. Contingent | — | 1 |
| 2. | Southern Dist....<br>M. & C. District | — | 1 | 5. | Nagpore Force<br>Central I. Regts. | — | 1 |
| 3. | Mysore Division<br>Ceded District... | 1 | — | 6. | British B. Division | — | 1 |
| | | 2 | 1 | | | — | 3 |

For the Bombay Army—

1 Surgeon-General, Army Medical Department
1 Secretary to Surgeon-General, Indian Medical Department
} At Head Quarters.

The four circles of medical superintendence will be distributed as follows, each being held by a Deputy Surgeon-General:—

| | | Army Med. Dept. | Indian Med. Dept. | | | Army Med. Dept. | Indian Med. Dept. |
|---|---|---|---|---|---|---|---|
| 1. | Presidency Dis ..<br>Belgaum ... ...<br>Aden ... ... ... | — | 1 | 3. | Northern Division ... ...<br>Mhow Division | 1 | — |
| 2. | Poona Division... | 1 | — | 4. | Sind District ... | — | 1 |
| | | 1 | 1 | | | 1 | 1 |

With the exceptions which are named below, all those officers will be relieved from any civil administrative duties they may have hitherto performed.

The Deputy Surgeons-General of the Eastern Frontier District and of the British Burmah Division will, in addition to their military duties, exercise the civil medical administration of their respective provinces, and will also perform the duties of Sanitary Commissioner in them.

The Deputy Surgeons-General of the Punjab Frontier Force and of the Sind District will exercise the civil medical administration of those provinces.

After making provision for the civil medical administration of the remaining provinces of British India, the establishment for which will be duly notified in the proper department, there will remain, below the rank of Surgeon-General, in excess of the establishment to be maintained for all duties—

*Army Medical Department.*

2 Deputy Surgeons-General.
3 Superintending Surgeons-Major.
2 Secretaries to Surgeons-General.
1 Statistical Officer to Surgeon-General.

*Indian Medical Service.*

6 Deputy Surgeons-General.

Orders have been already issued by her Majesty's Government for the withdrawal of the surplus administrative officers of the Army Medical Department.

With a view to provide for the retirement, on favourable terms, of the surplus officers of the Indian Medical Service, the Right Honourable the Governor-General in Council is pleased to offer to the Surgeons-General and the Deputy Surgeons-General of the three Armies their retirement on the extra pension of their grade, with an honorary step of rank, notwithstanding that they may not have completed the qualifying service of these pensions.

The number of retirements in each Army will be restricted to two.

The option of retirement will be given in order of seniority; but applications to retire, which must be made to the Military Department of the Government to which the officer belongs, cannot be accepted after March 1, 1880.

◆

# Obituary.

## DR. THOMAS FAIRBANK.

At the early age of thirty-six, Dr. Thomas Fairbank, Physician to the Queen's household at Windsor, died on Feb. 26, after an apoplectic seizure. At the University of London M.B. Examination, in 1864, Dr. Fairbank was placed in the First Honours division, receiving gold medals in Medicine and Forensic Medicine. He pursued his medical curriculum at St. Bartholomew's Hospital, and was recommended to succeed the Queen's surgeon at Windsor, Mr. Brown, by the late Sir James Clark and Sir James Paget. He held the appointment, also, of Surgeon to the Royal Family and household at Windsor Castle, and to T.R.H. Prince and Princess Christian and their household at Frogmore.

Dr. Fairbank was widely esteemed, and his death has created a feeling of profound grief in the neighbourhood of his practice.

## DR. EDWARD COPEMAN, F.R.C.S.

By the death of Dr. Edward Copeman, of Norwich, the medical profession is deprived of one of its most promising provincial members. As a consulting physician Dr. Copeman had a most extensive practice, and to obstetric specialists his name will be long familiar from association with many operations in midwifery, and particularly from his advocacy of the use of the vectis. The deceased was consulting physician to the Norfolk and Norwich Hospital, having been elected to this post on resigning the duties of physician to the institution, a position he entered on at the age of forty-two, in 1851. Dr. Copeman was made a Fellow of the Royal College of Physicians, London, in 1871, and Member in 1859. He graduated M.D., King's College, Aberdeen, 1847, and took the F.R.C.S. Eng. by examination in 1845, the date of his diploma as Member being 1832. His commencing studies were conducted on the good old plan of pupilage to a practitioner, Mr. Arthur Brown, of Norwich, having been to him *in loco doctoris*. Subsequently he entered at St. George's Hospital.

Dr. Copeman held numerous and responsible appointments, was President of the East Anglian Branch of the British Medical Association in 1863, and presided at the Norwich meeting in 1874. His literary labours were extensive and valuable. His first and last essays dealt with blood-letting. His most important contributions to medical science, however, are a series of papers on dilatation of the os uteri in treatment of vomiting in pregnancy. These have attracted very great attention in this country and America, and also on the Continent.

Dr. Copeman's social qualities were of the brightest; they endeared him to his friends, so that the favoured circle who were his immediate associates will only feel more keenly the loss sustained by the whole profession through his death.

## ROBERT MAUDE MAGINNISS, M.D., &c.

On the 28th ultimo, at his residence, 158 Camden Road, London, after a few hours' illness, in the first blush of his professional career, Dr. Robert Maude Maginniss passed away. He was the youngest son of the Reverend Charles Maginniss, Rector of Dromore, Ireland, and grandson of the late Sir John Maginniss, M.D., of Londonderry. Dr. Maginniss was educated at the Diocesan School, Monaghan, from which he entered T.C.D., and after a highly successful University career he graduated in Art as First Senior Moderator and First Gold Medallist in Natural Sciences. In the following year took the M.B. degree, obtaining a bright place. He took first place in the examination for B.Ch.; last year he took the M.D. of his University. Dr. Maginniss having taken a practice in London, his many social and professional attainments soon brought him to the front. For some six weeks past he suffered from headache, which did not interfere with his professional labours or alarm his friends. However, on the morning of the 28th he had an apoplectic seizure which proved fatal, and he died on that evening at the early age of twenty-five. Aneurism of the basilar artery is now known to have caused the headache, and a rupture of the aneurismal sac to be the cause of death. He leaves a young widow, to whom he was only married ten months, to mourn his loss.

◆

## DR. DONOVAN.

We greatly regret to announce the death, on Sunday week, at an early age, of one of the most distinguished physicians of the South—Dr. Daniel Donovan, of Skibbereen. Dr. Donovan was the son of the eminent physician of that name who rendered such signal service to the people during the great famine. He himself was a devoted friend of the poor, and his services during the recent outbreak of German measles at Cape Clear came prominently before the public. Estimable and beloved in all the relations of life, Dr. Donovan's death has been heard of with intense sorrow throughout all the west of the county of Cork.

# Correspondence.

## DELICATE CHILDREN IN WORKHOUSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The condition of our sickly workhouse children was noticed in a very sympathetic spirit in your paper, and also in the *British Medical Journal*, in connection with a little paper of mine on the subject. Both writers adopted a very similar line of argument—that these children require better treatment—that as preventive and curative it would eventually repay the State, and both say all this can be well given in the workhouse, and they deprecate my idea of special institutions.

Now I am not only a pitiful Christian woman, but a sorely taxed rate-payer, and not at all likely to wish to increase a burthen already more than heavy enough on myself and my tenants. My proposition would, in Ireland, cost less than theirs. Permit me to observe the question has three sides. 1. Medical. 2. Moral. 3. Economic. We have to consider the children and the ratepayer too. The suggestions of the doctors, of course, meet the medical difficulty. My friend, Dr. Laffan, has got his Board of Guardians to behave most justly and liberally to his patients; but even that model board might rebel, if a number of sickly, as distinguished from sick children, were transferred from the house to the hospital side, where they would cost in the proportion of five to three shillings. I believe the actual cost per head is a few pence less than three shillings, but the proportion may be stated as three to five in most Irish workhouses.

The Afflicted Persons Bill, introduced for Ireland by Count Moore, M.P., in 1878, permits any pauper to be sent for health or training to any suitable place selected by guardians, provided he or she does not cost more than in workhouse.

The Industrial Schools Act supplements from other sources the difference in cost of maintenance between poor-house and industrial school expenditure. Mr. Lentaigne has published very telling statistics bearing on the results he obtained from good food among the children transferred from poor-houses and industrial schools.

I think these two facts prove that if the Industrial Schools Act were modified so as to admit sickly children, the said children would get better treatment for the same cost, and the ratepayers would not suffer. No one at all familiar with workhouses could wish to keep children there, where they are of necessity exposed to the contaminating influences of the immoral mothers of many of the children, and to the company of tramp children. Of course you know professed tramps patronise the workhouse in bad weather, and the children are naturally thrown together. Supposing my clients were removed to the hospital side and removed from the tramp children, there is another unpleasant fact—there being hardly any able-bodied virtuous women in a workhouse, the bulk of hospital attendants are women who have lost their virtue, and surely these are very unfit to be about children.

In Ireland I would like to see portions of the industrial schools near Dublin, Cork, and Belfast set aside for sickly children. By sending them to the hospitals in these cities for treatment and inspection periodically there need be no hospital staff at institutions. The religious orders trained to hospital work meet the Catholic side of the question, and surely Protestant philanthropy, wealth, and intelligence can cope with its smaller number of Irish poor. Boarding-out and denominational orphanages and ordinary industrial schools would meet the case of my clients when once a healthy mind and body had been built up by the meat, milk, fresh air, soap and water we give our own children. Will you try and get your profession to speak out on the matter and so reach those in high places who would naturally distrust a woman quite ignorant of medical science?

Faithfully yours,

MARY A. O'CONNELL.

◆

## CHEMISTS IN PRACTICE.

### TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In connection with your protest against the extensive counter practice indulged in by chemists, and the readiness some of them exhibit to undertake the treatment of cases of injury which called for the most skilled attention, let me draw your attention to a recent instance in point. A child was brought to a chemist named Owen, living in the Seven Sisters Road, who told the mother "he had been in practice as a chemist a great number of years, *that he was better than fifty doctors*, and that the child was quite safe in his hands." He next gave practical proof of the absurdity of his pretensions by prescribing a mixture and powders, and continued his treatment for a week, by the end of which time the patient was so alarmingly ill that it was deemed advisable to invoke the aid of a local practitioner. Not unnaturally he refused to accept the responsible task of undoing the evil already effected by the unqualified agent, and advised that the child should be taken to a hospital. This was done, and death occurred the day after its admission. The post-mortem revealed nephritis and advanced jaundice; and in evidence it was insisted on that the life of the little victim had probably been sacrificed to the grasping inefficiency of the chemist. The coroner was emphatic in his condemnation of the extensive practice carried on by these self-appointed practitioners, to whose door he laid the death of many unfortunate children.

Now, Sir, since parents *will* be fools, does it not seem that the only plan to pursue is to curb the fatal consequences of their unwisdom by making it as criminal for a chemist to poison his customers as it is for a grocer to adulterate his sugar? The least that can be done in this matter is to protect the helpless children who are given up to the tender mercies of the unconscientious dispensers of physic. It deserves notice that the jury before whom the case I have cited was heard, expressed their conviction that "censure would be useless, since the mischief was done." Must it follow that the freedom to slay irresponsibly shall be left in the hands of those who are deaf to the calls of mercy?

I am, Sir, yours, &c.,

W.

# Medico-Parliamentary.

## HOUSE OF COMMONS.—MONDAY, MARCH 1ST.

### THE ARMY MEDICAL SERVICE.

COLONEL STANLEY, in moving the Army Estimates for the ensuing year, said:—There is a great concurrence of opinion in favour of the medical warrant as it now stands. I think the liberality with which, by the consent of the Chancellor of the Exchequer, the Government has been enabled to deal with the subject has been distinctly a benefit. I am glad to hear that it has been successful in attracting candidates of a better class than those who have been brought into the army for many years past. There seems to be a consensus of opinion that the warrant is so far liberal that, if it do not attract candidates, nothing will. There have been two examinations of candidates since December last, when the warrant was issued. At the first, seventy-two candidates passed out of seventy-six who offered themselves for examination; and on the second occasion forty-two candidates presented themselves, of whom thirty-five came up to the required standard and were accepted. Thus within the space of little more than two months there were one hundred and eighteen competitors, of whom one hundred and seven were successful. Both in South Africa and in Afghanistan the generals in command have spoken in the highest terms of the efficiency, zeal, and self-devotion of all ranks of officers; and I am afraid that in this respect there is even melancholy evidence in the large numbers who have succumbed to hard work, especially among the Indian forces. I must refer to the loss which the medical service and the medical world in general have sustained by the death, at Sherpur, of Deputy Surgeon-General Porter, an officer whose arrangements for all the medical duties of the campaign left nothing to be desired. He leaves, both among the medical world and those who are his countrymen, a reputation to which his friends may look back with satisfaction, and a memory which will be dear to all those who knew him. There is another point in connection with the medical service to which I should like to draw attention. In the recent attack on Secocoeni's camp, the ambulances were for the first time fully organised; and it is satisfactory to know that this was attended by the best results, under the direction of Surgeon-Major Hector. It is important that I should draw attention to this, because it is a marked feature in field medical organisation. The official report of the principal medical officer states that so efficiently and rapidly did the corps perform its duty, that no wounded man was left two minutes on the ground before he was taken to the dressing station. Subject to certain conditions, exchanges are now as absolutely free as in the combatant branch. The only exception is that when a medical officer becomes invalided from such a climate as India, he is prevented from going into a similar climate.

The concession of forage to surgeons has been treated by almost all of them as a genuine and welcome concession. We have also introduced a system, when there is not work enough to employ an army medical officer, to engage the services of others at a lower rate of pay. Twenty-one medical officers on half-pay and six militia medical officers have been appointed to these stationary posts. The admissions into the hospitals were at the rate of 827 per 1,000, and the rate of deaths was 7·37, which, compared with the rates of previous years, shows that the admissions into the hospitals have slightly increased. The increase of the rate at Bengal was due to cholera, and the increased sickness at Gibraltar is stated to have arisen partly from the prevalence of paroxysmal fever among the troops sent thither from Cyprus. With regard to Cyprus, there is a marked improvement in the health of the troops in that island, both the rates of sickness and of death having decreased during the past year.

### CORONERS' FEES.

Mr. O'Clery asked the Attorney-General for Ireland whether the Grand Jury of Carlow had a discretionary power to disallow the coroners' fees for the holding of inquests in cases where death resulted from drunkenness; in case the Grand Jury have not that power, whether the coroner can include such disallowed fees in his next presentment; and if such powers are invested in Grand Juries, will he explain how is it that in the forms for returns to Government by coroners there is a separate column for such cases?

The Attorney General for Ireland.—Under the 9 and 10 Vic., cap. 37, the Grand Jury have the duty cast on them of examining and approving of the coroner's abstract and account of the inquisitions held by him; and they are empowered to examine the former by oath as to their correctness; and it followed that in taking their steps they are clothed with a discretionary power. If the former is dissatisfied with the action of the Grand Jury on any point, it is to him to apply to the judge of assize on the subject. In reference to the last paragraph of the question, I may draw the attention of the hon. member to the fact that in the Government returns the column containing those cases, in which the verdict was "death from excessive drinking" is ranged under the more general heading of "death from natural causes."

◆

## THE MEDICAL REFORM BILLS.

The Select Committee held its first meeting on Monday last to re-open its deliberations on the four Bills which were submitted to it last session, and again in the present year; but owing to the untimely dissolution of Parliament another session will probably pass without anything being done to further the Medical Acts Amendment Bill. The *personnel* of the Committee is exactly the same as last year, with two notable exceptions—*i.e.*, Mr. Forster ceases to be its chairman, and Mr. Lowe replaces Dr. O'Leary. Mr. Forster is felt by all parties to be a loss to the cause of medical reform, and the more so because by his secession the Committee loses much of the advantage derivable from his study of the subject last year. Lord George Hamilton, who takes Mr. Forster's place, possesses everyone's confidence; but being a minister engrossed with all the detail of an important department, and with a responsible Parliamentary position, it is feared that he will not be able to give a fair share of attention to his Chairmanship of this Committee. Moreover, it is apprehended that he, representing as he does the Government Bill, must be unfavourable to the principle of direct representation, and may, as Chairman, incline the balance of opinion against that inevitable and indispensable concession. However, we are satisfied to know that Lord George Hamilton is thoroughly in earnest to pass a Bill, and will do his best to meet the reasonable demands of all parties, so long as those demands are consistent with effectual medical reform. In Mr. Lowe the Committee receives a special representative of the London University, and of high-class medical education. We may assume that his proclivities are favourable to a short curriculum, a cheap license, and a strict examination, and, we fear, against a full arts qualification for the University M.D.

We understand that it is intended to hasten the completion of the evidence, and to report to the House as soon as may be.

◆

## THE ELECTIVE RIGHTS OF THE FELLOWS OF THE IRISH COLLEGE OF SURGEONS.

The Council of the College had under consideration at its meeting last Thursday the recommendation adopted by the College at large at its recent special meeting, to the effect that legal advice should be taken as to whether the right to elect the representative of the College in the General Medical Council rests with the College at large or with its Council. It has been decided to comply with that recommendation, and the drawing of a case for the opinion of legal advisers has been remitted to a committee and to the solicitor of the College. The case will be submitted to the Council for approval before it is laid before its adviser.

◆

The death-rate from the seven principal zymotic diseases in the large towns ranged from 1·1 in Leeds and Birmingham, to 7·6 and 9·7 in Nottingham, and Plymouth. Measles showed the largest proportional fatality in Nottingham, Plymouth, and Hull; scarlet fever in Sunderland, Nottingham, Brighton, Norwich, and Newcastle-upon-Tyne; and whooping-cough in Plymouth and Newcastle-upon-Tyne. Small-pox caused 13 more deaths in London, 3 in Dublin, but not one in any of the other large towns.

## Medical News.

**Indian Medical Service.**—The following is a list of candidates who were successful at the February competitive examination held at Burlington House. Fifty-two candidates competed for twenty-three appointments; forty-eight were reported qualified:—

| | Marks. |
|---|---|
| Simpson, J. | 2,470 |
| Whitwell, R. R. H. | 2,395 |
| Lakis, C. P. | 2,385 |
| Waddell, L. A. | 2,250 |
| Dimmock, H. P. | 2,173 |
| Shewan, G. | 2,060 |
| Maitland, C. B. | 2,040 |
| Vaid, C. C. | 2,040 |
| Macdonald, T. R. | 1,981 |
| Clarke, J. | 1,980 |
| Spencer, D. B. | 1,975 |
| Park, P. D. | 1,965 |
| Mulroney, T. R. | 1,950 |
| Browning, W. B. | 1,945 |
| Divecla, F. R. | 1,920 |
| Canna, R. H. | 1,907 |
| Henderson, C. | 1,965 |
| Dymott, D. F. | 1,909 |
| Thompson, C. M. | 1,900 |
| Adams, A. P. | 1,865 |
| Evans, J. W. | 1,815 |
| Leonard, J. | 1,810 |
| Rundle, C. S. | 1,765 |

**Tit for Tat.**—A medical practitioner, urgently wanting patients, and not understanding the difference between attracting and disgusting, circulates post-cards through the city addressed to any gentleman of sufficient eminence to draw his attention, on which he offers his services to cure them of fits, falling sickness, epilepsy, and all the ills, too disagreeable to mention, that flesh is heir to; closing with the agreeable assurance that he will treat them in perfect confidence. Imagine his disgust on receiving from a witty lawyer this response, also spread on a post-card:—"Dear Sir,—I offer you my services to defend you on your trial for murder, arson, robbery, larceny, malpractice, criminal abortion, indecent assault, body snatching, and obscene communications. I can secure, if not your acquittal, at least the mitigation of punishment, every time. N.B.—This post-card is strictly confidential."—*Albany Law Journal.*

# NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

## THE COPLAND FUND.

*To the Editor of the* MEDICAL PRESS AND CIRCULAR.

SIR,—In closing the above Fund, I beg to state that the whole sum collected amounted to £101 5s., which I have handed over to Mrs. Copland, and I am desired, on the part of the Committee, to thank the subscribers and the Editor of the *Medical Press and Circular* for their kind assistance.

I remain, Sir, yours truly,
R. H. SEMPLE, M.D.,
Torrington Square, March 1, 1880. Treasurer of the Fund.

**A MEMBER.**—The election took place on Monday week, and was unanimous.

**HARVEIAN SOCIETY OF LONDON.**—Thursday, March 18, at 8.30 p.m. Mr. A. J. Pepper, "A Case (and prepared specimen) of Malignant Disease of the Hip."—Mr. Knowsley Thornton, "The various Methods of dealing with the Pedicle in Ovariotomy."

**MR. H. G SIMPSON.**—The only remedy is by a process at law. Every registered practitioner is entitled to recover through the county court, but we do not consider with you that this is the only advantage conferred on the profession by the General Medical Council. You are quite right, even though it does *not* effect any material benefits, it is a great boon to possess a counsel. Whether as much, and as good work could be done without the parade and expense attendant on the meetings at present, we cannot undertake to say in this place. Consult the recent numbers of the *Medical Press and Circular*. To your last inquiry, emphatically *no*.

**CURIOSITAS.**—It was published by the Sydenham Society in 1849. The translator, Dr. Francis Adams, was selected on account of his intimate acquaintance with the history of primitive medicine. You have been rightly informed on the principal fact, but it is not true that the doubt expressed by some of Hippocrates' existence has ever been established beyond dispute. The "genuine" works mean those of whose authorship there is no reasonable doubt. You cannot do better than read the Sydenham edition. 2. The New Sydenham is the existing Society. 3. "Billroth's Surgery," 2 vols., is the outside title. The translation by Hackley is from a later German edition.

**DR. MARTIN.**—The "Students' Number" is out of print, but we have instructed our publisher to send you an office copy.

**A COLONIAL.**—You will find little difficulty if proposed and seconded by two Fellows of the Society.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—To-day (Wednesday), at 5 p.m., the Croonian Lectures: Dr. Cayley, "On some Points in the Pathology and Treatment of Typhoid Fever."

**MR. W. D. H.**—They have been sent as requested.

**HUNTERIAN SOCIETY.**—This evening, at 7½ p.m., Council Meeting.—8 p.m. Dr. F. Warner, "On a Case of Athetosis, associated with Epilepsy.—Mr. J. Startin, "On a Case of Elephantiasis."—Dr. Carrington, "On Cancer of the Bile-duct; Fatal by Suppuration of the Liver."

## KNOT IN THE UMBILICAL CORD.

*To the Editor of the* MEDICAL PRESS AND CIRCULAR.

SIR,—About three months ago I met with the following case—the only one out of about 900 labours which I have attended:—

I was called in by a midwife and found a shoulder presentation with a long loop of the cord prolapsed, which had been down for about two hours, and was cold and pulseless, and on the middle of which was a single knot, firmly drawn. I turned and delivered a dead, well-developed child. Cord about 2 feet long and very smooth.

Faithfully yours,
March 1, 1880. W. J. WELDON.

**DR CHARTERIS** will please receive our best thanks.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—Friday, March 12, at 5 p.m., the Lumleian Lectures: Dr. W. Roberts: "Researches on the Digestive Ferments and the Preparation and Use of Artificially Digested Food."

**CLINICAL SOCIETY OF LONDON.**—Friday, March 12, at 8½ p.m., Mr. Eve, "On a Case of Impacted Fish-bone in the Œsophagus, penetrating the Diaphragm and Pericardium, and Wounding the Heart."—Dr. Greenhow, "On a Case of Typhoid Fever, associated with Acute Nephritis and profuse Hæmaturia, without Dropsy."—Dr. Buzzard, "On a Case of rapid and almost universal Paralysis, involving 'the four Extremities, both sides of the Face, Respiration, and Deglutition; Recovery."—Mr. Eve, "On a Case of Fracture extending through the Temporal Bone."—Mr. Clutton, "On a Case of Femoral Aneurism; Ligature of the External Iliac Artery; Recovery."—Dr. Crocker will exhibit a Case of "Herpes Iris."

## SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

*To the Editor of the* MEDICAL PRESS AND CIRCULAR.

THE following has been sent us for publication by the Hon. Sec. of the Poor-law Medical Officers' Association:—

SIR,—I am directed by the Local Government Board to advert to their letter of the 12th inst., and further to acquaint you, for the information of the Council of the Poor-law Medical Officers' Association, that inquiry having been made of the Guardians of the Tenterden Union respecting the case of M. Terry, formerly Medical Officer of that Union, the Guardians have explained that they entertain objection to the system of superannuation, especially in cases where the whole time of the officer is not devoted to the duties of the office. As the Council are probably aware, the initiative in these cases rests with the Guardians, and the Board have no power to insist upon a superannuation allowance, even where it might seem to them that a proper case for superannuation had been made out.

Yours, &c.,
Local Government Board, Whitehall, S.W., V. F. ROTTON,
February 27, 1880. Assistant Secretary.

**MR. CRIPPS LAWRENCE.**—Thanks; received, and marked for early insertion.

**A HATER OF SHAMS**, the *Standard* has opened its columns to a discussion of the charges against St. John's Hospital for Diseases of the Skin. See letter of Dr. Hoggan on Wednesday last in that paper.

**L.K.Q.C.P.**—A slight affection of the kind named would not disqualify. Very strict medical examination. Get Parke's Hygiene, Aitken's Medicine, and Gant's, Bryant's, or Holmes's Surgery; but surgery not so important as there will be lectures at Netley on military surgery. Must read some of the class-books for entrance.

◆

## VACANCIES.

Carmarthen County Infirmary.—House Surgeon. Salary, £125. Applications to the Secretary, King Street, Carmarthen, before March 31.

Chatham.—Assistant House Surgeon for the St. Bartholomew's Hospital. Salary, £80, with board. Applications to the Clerk of the Trustees before April 14.

North Staffordshire Infirmary.—House Physician. Salary commencing at £100, with board. Applications to the Secretary, at Hartshill, before March 24.

Queen's University in Ireland.—Examinership in Medicine; Salary, £100. Examinership in Surgery; Salary, £100. Examinership in Midwifery; Salary, £75. Examinership in Materia Medica; Salary, £75. Examinership in Medical Jurisprudence; Salary, £75. Candidates must address the Secretary on or before March 16. (See Advt.)

Stockport Infirmary.—House Surgeon. Salary, £100, with board. Applications to the Hon Sec. by March 13.

## OVARIOTOMY AND ANTISEPTICS.

By WILLIAM STOKES, F.R.C.S.,
Surgeon to Richmond Surgical Hospital, &c., &c.

I DESIRE to draw the attention of this Society to the two last cases in which I performed ovariotomy. I do so, not so much on account of the result in both having been successful, or because there was any special feature of pathological interest in either of them; but mainly because, though the result was the same, the antiseptic measures adopted in both cases widely differed. They thus furnish an opportunity for the discussion, one which has not yet been raised in this Society, of what we must admit is still an unsettled question, namely, the therapeutic value of the employment in the operation of ovariotomy, as well as in other operative measures, of antiseptics, in the manner first suggested and practised by Prof. Lister.

I have considered ovariotomy to be the most fitting operation to bring forward in connection with this subject, as being in every sense a procedure that has tested most crucially, if I might so express it, the merits of antiseptic surgery.

CASE I.—*Bilocular Ovarian Cyst—Ovariotomy—Recovery.*—Winifred B., æt. 19, a dark-haired, florid complexioned, well-nourished, unmarried girl, was admitted into the Richmond Surgical Hospital under my care on Jan. 22nd, 1879. She had been suffering from an abdominal enlargement for two years previously. She first consulted me in December, 1877. For two or three months previous to this she had suffered from amenorrhœa. On examination I found a distinct enlargement, chiefly on the right side. On closer investigation I satisfied myself that the case was ovarian, an opinion in which Dr. Kidd and my other colleagues coincided. The tumour was of such comparatively small size, and the patient's health so unaffected by it, that it was considered undesirable to undertake any operative interference until I had an opportunity of watching the progress of the case for some time longer. I may mention that I wrote to Mr. Spencer Wells at this time in reference to the case, with the object of obtaining his opinion as to the desirability or otherwise of operating on ovarian tumours at a very early stage of their development. In an interesting reply, which, with his usual courtesy he promptly sent, Mr. Wells quite concurred with me and my colleagues as to the desirability of postponing operative interference until the tumour got larger. I regret extremely that I have mislaid the letter in which his reasons for postponement were so clearly and forcibly given. The patient accordingly returned to the country, but I had an opportunity of seeing her from time to time, and watching the progress of the case. This consisted in a steady gradual increase in its dimensions up to the time when she was admitted into hospital in January, 1879. The circumferential measurement at the umbilicus was then 41¾ in., and from the xiphoid cartilage to the pubis 16 inches. Three days after the patient's admission into hospital I performed ovariotomy; and as there were few adhesions, and the cyst bilocular, little difficulty was experienced. The pedicle was very short and thick, and was secured by an antisepticised silk ligature. The contents of the cyst were very remarkable; the fluid being as clear as spring water. The cyst was an unusually thin one. The strictest antiseptic precautions were used previous, during, and subsequent to the operation. The antiseptic employed in this case was thymol; one which I have not found inefficient, and which, in my opinion, ill deserves the wholesale condemnation it has received at the hands of some operating surgeons. However, since phenol, a purer form of carbolic acid, was recommended to me last June by Prof. Lister, when he was in Dublin, thymol has been entirely discarded by me and my colleagues at the Richmond Hospital.

After the operation the patient rallied well. For the first three days her chief, indeed only nutriment, was iced milk. On the fourth day there was a considerable hæmorrhage from the vagina; a circumstance which I had not had occasion to observe in any of my previous ovariotomies, and which I confess at the time I was not prepared for. This form of hæmorrhage, termed "uterine epistaxis," is

---

(a) Read before the Surgical Society of Ireland.

not looked upon by any means as an unfavourable circumstance after ovariotomy. At the same time that this hæmorrhage occurred there was a marked rise in temperature, rising to 102·8 F. This also naturally caused me some anxiety; however, the following morning the temperature and pulse both fell, and from that date the convalescence of the patient proceeded without interruption.

Case II.—*Multilocular Ovarian Tumour—Ovariotomy—Recovery.*—Jane T., æt. 33, a tall fair-complexioned, well-nourished, brown-haired, blue-eyed, married female, who had borne nine children, was admitted into the Richmond Surgical Hospital under my care in the early part of last June, having been recommended to my care by Dr. O'Kelly Nolan, of Gort. In June, 1876, she first observed an abdominal enlargement, which during the following seven months remained apparently stationary. In January, 1877, the tumour commenced to increase perceptibly in size, and went on increasing during the following eighteen months, until it reached the dimensions it had on her admission into hospital; the circumferential measurement at umbilicus then being 38½ inches, and from ensiform cartilage to symphysis pubis 17 inches. The menstruation during the time the tumour was developing remained quite regular. Early in February she had an attack of peritonitis, which yielded to suitable treatment. The tumour was globular, irregular on the surface, nodular in fact, more prominent on the right than on the left side, and from the facility with which it could be pushed from one side of the abdomen to the other, I considered it probable that the pedicle was a long one. The existence of ascitic fluid was also recognised. There was no œdema of the lower extremities. On June 28 I performed ovariotomy. The operation was done with rigid antiseptic precautions, phenol being on this occasion used, owing to the large amount of adhesions, and also from the fact of the tumour being practically a solid one, for it consisted of a congeries of small cysts about the size of grapes, with walls so thin that they broke down almost immediately on being touched by the finger. The cysts were so numerous that it was impossible to remove the fluid contents with the ovariotomy trochar. I then made an incision into the tumour. In doing this it was unfortunately impossible to prevent a small quantity of fluid entering the peritoneal cavity. Finally, I had to enlarge the original incision, both upwards, to a point fully an inch and a quarter above the umbilicus and downwards, almost to the pubes. After much difficulty I eventually succeeded in dislodging the enormous semi-solid mass, and found it as I had anticipated, attached by a long thin slender pedicle. This was then secured by strong carbolised silk cord, and returned into the abdomen. The "toilet of the peritoneum" was, owing to some of the cystic fluid having escaped into the peritoneal cavity, conducted with minute care. A glass drainage tube was then inserted at the lower angle of the wound. Of the other details of the operation there is nothing, I think, specially noteworthy, and the same may be said as regards the subsequent daily progress of the case. The wound healed immediately, not a single drop of pus having ever soiled the dressings. On the seventh and eighth days after operation, the patient complained of much abdominal pain, and both pulse and temperature curves rose accordingly. I believe this to have been due altogether to flatulence. The day following the pain ceased, pulse and temperature fell, and nothing further occurred to interrupt the progress of the case towards complete recovery. On August 4th the patient returned to her family. In none of the ovariotomies I have performed or witnessed, have I seen a case surrounded with greater difficulties, one requiring so large an incision, or a longer time before the operation could be completed. Having regard to these circumstances, as well as to the almost universal adhesions, the tearing of them, the hæmorrhage, the escape of fluid into the cavity of the peritoneum, the necessarily protracted sponging of the intestines, and the "valleys of the pelvis," and then the primary union of the wound, and almost uninterrupted recovery of the patient, we may put to ourselves the question, Did not antiseptics, or I should rather say "Listerism," play a chief rôle in bringing about the result? He would be, I think, a hardened and hopeless sceptic who would answer the query in the negative.

Before, however, entering on the antiseptic question, there is a circumstance connected with the cases I have just detailed, which suggests the consideration of another unsettled point, namely, the relative value of pulse and temperature curves in forming an estimate of the probable results of ovariotomy, as well as other serious operative measures.

The pulse and temperature curves were, it will be observed, in accord throughout the convalescence of both patients. Most ovariotomists attach more value to temperature curves, than to pulse curves. Mr. Lawson Tait, however, is an exception to this rule, and is of opinion that as regards prognosis the pulse curves are of greater importance, as a rise in them more certainly indicates "something wrong." From my observations of the progress of ovarian cases after operation, as well as other surgical cases requiring operative interference of a serious nature, I am disposed to think this latter view is the one, in the majority of cases, likely to be correct. In a case in which I had recently occasion to remove an enormously enlarged uterus, together with both the ovaries, the pulse curve rose to an extreme height, whereas the temperature curve hardly rose above the normal standard. Immediately previous to the patient's demise it, on the contrary, fell below that point. There was then no accord between the phenomena of pulse and temperature. It is of interest, therefore, to note, that as in essential fevers, functional from organic lesions can, as a rule, be differentiated by observing the want of accordance of phenomena, so in surgical fever the observance of the existence, or the absence, of accordance, may materially aid the surgeon in reference to prognosis. We must not rely, therefore, too much on any one branch of phenomena in estimating the probable result of cases of surgical fever following such procedures as ovariotomy, hysterectomy, resection of the larger articulations, or amputations of the limbs.

I stated at the commencement of this communication, that the question of antiseptics, which these cases suggest, is still unsettled. This, I think, must be admitted when we recall the fact that at the comparatively recent International Medical Congress at Philadelphia, the verdict given there was "Not proven," and that in Great Britain, Germany, and France, so many surgeons of acknowledged ability are found who are not only passively but actively hostile as much to the theory as to the practice of what, to prevent any misconception we may term "Listerism." Some of these, strange to say, while antagonistic to the practice, oddly enough admit and adopt the views of the germ theorists. I need only recall Mr. Savory's denunciation of "Listerism" last year at Cork as a proof of this. In that lecture he distinctly admitted that atmospheric organisms were a cause of putrefactive changes in wounds.

Speaking of septic atmospheric particles, he observed, "that they are organic, and possessed, at least, of the fundamental attributes of living matter seems proven by their behaviour, and by some of the tests that we can apply to them. It is enough for us that they are septic; that they can produce and promote putrefaction; and further, that fluids so changed by them may provoke those terrible effects which are only too well known as blood poisoning." In admitting the existence of atmospheric agents of putrefaction, commonly called germs, it appears to me Mr. Savory admitted everything that Prof. Lister wishes us to accept in reference to the theory on which his practice is based, but notwithstanding this full admission, he oddly enough condemned in terms of withering sarcasm and scorn, the adoption of measures which undoubtedly have at all events a neutralising effect on these deleterious agencies.

Though the germ theory is comparatively of recent origin, the injurious effects of the admission of air to wounds were recognised by surgeons of remote antiquity.

In the aphorisms of Hippocrates will be found the following remarkable statement:—"Air," he observes, "is an enemy to the brain, the bones, the nerves, and to our nature in general."—Lib. 5, Ahor. 17. In connection with ovariotomy, Mr. Savory's condemnation of Listerism was all the more remarkable to me, on learning of the signal success that has been obtained in ovariotomy at St. Bartholomew's Hospital, of which he is one of the surgeons, a success which I am informed on trustworthy authority, dates from the time that Listerism was introduced there by the surgeons who practise the operation under discussion in that institution.

It is not my intention to even attempt to discuss in any exhaustive way on the present occasion, at all events, the arguments that have been adduced by the surgeons who are hostile to "Listerism." A few statements and objections made by them, however, deserve a passing notice, as they are frequently adduced by the opponents to rigid antiseptic practice. Mr. Lawson Tait, in a recent very important communication at the Medico-Chirurgical Society, observed:—"If the views of the germ theorists be correct, no surgical operation could be successful without rigid antiseptic precautions." Such statements as that may, I think, be replied to by observing that neither Prof. Lister nor any other germ theorist has ever, as far as I am aware, put forward the doctrine that atmospheric organisms are the *sole* causes of putrefactive changes in wounds; and assuming that they were, has it ever been put forward or even suggested that all wounded persons must necessarily be equally, or at all, affected by them? When such an alleged difficulty as that I have just mentioned is put forward, it is not too much, I think, to say that it possesses many of the attributes of a "man of straw," and when a structure of that sort is erected, it is easy enough to knock it down, and it is curious to observe how many persons there are of ability and experience who apparently delight in the amusement. But when it is not recognised as such, these difficulties and objections will at once arise in the minds of many, and surgical progress may in consequence be retarded, or for a time completely arrested.

Prof. Wood's difficulties in this matter are as follows:—"How is it," he observes, "that if bacteria have a power so terrible in their effects, in 999 cases of wound out of 1,000 they are unable to exercise it?"

In answer to this I would say that in the first place the proportion of cases mentioned of wounds that, according to him, are observed to be unaffected by these organisms that are "so terrible in their effects," is, in my opinion, considerably over-stated. The proportion of cases unaffected is doubtless very large, but is there in this fact anything to make us question the germ theory? It appears to me one might just as well doubt the existence of the poison of typhus, small-pox, or scarlatina, because we observe hundreds of physicians, students, and nurses are daily brought into contact with such cases, and that only a very small proportion of them are injuriously affected by such contact. Again he says, "How is it that a patient may die of pyæmia or septicæmia, self-poisoned without an external wound at all, the source of infection being a deep-seated abscess far secluded from contact with the air, and that bacteria may exist in abscesses originating inwardly, and yet no blood-poisoning ensue?

It may be stated in reply to this that it has never been affirmed by any germ theorist that atmospheric agencies alone bring about putrefactive changes in the animal economy. That there are other causes not yet demonstrated, not within our ken, which act, however, far less frequently is probable, nay, almost certain; but why should we refuse acceptance to what has been demonstrated and is known, because we can as yet only partly see through the mist?

The last difficulty Prof. Wood raises is, "How is it that wounds of the face cavities heal so quickly and well, and yet bacteria are found in number in the fur of the tongue, and the mucus on the surfaces of these cavities?" It is unnecessary, I think, to reply to this last objection. Had Prof. Wood read the lecture on antiseptics delivered in the Richmond Hospital last June by Mr. Lister, or the answer to Mr. Savory's strictures on antiseptic surgery by Mr. Thomson, published in the *British Medical Journal* for September 20, 1879, he would have found his difficulties on this point fully cleared up.

Mr. Tait has, alluding to Dr. Roberts's researches, which have gone so far to endorse Prof. Lister's views, in the communication already referred to, observed, "In rotting and decaying fruit the minute forms of life were confined to the decaying parts. How then can it be assumed that their invasion was the cause of the decadence of vital phenomena, while it appeared that such decadence, due to some unknown cause, excited the germs to do what during full vital action they could not effect?" It may perhaps be considered somewhat far-fetched to attempt the establishment of an analogy in the phenomena observed in a rotting apple and a wounded man, but there is a strong analogy, and Prof. Lister has alluded to it. He observes, "Healthy living tissue has the power of counteracting the development of these minute organisms, on the same sort of principle probably as the healthy plant can resist parasitic fungi. If a plant becomes enfeebled by cold, you see fungi developed on it, but if it becomes vigorous again the fungi leave it. The healthy tissue of the plant resists the growth of the fungi. Well, then the healthy living tissue of a wound—that is to say, if the tissues are perfectly free from irritation and disturbance, and have recovered from the damage done by the wounds, these tissues resist the development of the organisms." If the tissues near a wound cannot be kept healthy and free from irritation and disturbance, there will be observed a decadence to a greater or less extent of what, for want of a better term, has been designated "Vital Phenomena."

There is one more point—one out of many I should like to draw attention to now, did time permit—which I wish to mention, and that is the cases where, notwithstanding the most careful antiseptic precautions on the part of the surgeon, he fails to keep the wounds after operation aseptic. These cases may be divided into those where the skin was broken before operation, as in cases where sinuses existed, and the others where it was unbroken. As regards the latter, we must remember that the condition of receptivity to noxious influences producing septic poisoning is an ever varying one, being great in some and apparently *nil* in others, and that at present it may, and probably will, be different in the future. We have no means of estimating the powers of resistance possessed by those we operate on to the influences, intrinsic as well as extrinsic, which latter, at all events, exercise happily far less frequently now than formerly, so baneful an influence in producing septicism. In the former class of cases I believe it to be most difficult, in truth almost impossible, to keep the wound aseptic throughout. This difficulty has been fully recognised by Mr. Lister. But undoubtedly it is possible, by spoon scraping and applying phenol or chloride of zinc, to get for a time, at all events, a perfectly aseptic course. This was well exemplified in a case I operated on at the commencement of this session, where I had to amputate through the hip-joint for necrosis. In that case I succeeded in keeping the wound perfectly aseptic for eight days. I need hardly say what an undoubted advantage it is to avoid putrefaction during a period of some days following so serious an operation; in Prof. Lister's words, "tiding the patient over the critical period of greatest irritability of the wound, and greatest proneness to septic absorption."—*British Medical Journal*, Feb. 21. If this be true of amputations and resections, how much more likely is it to be applicable to hysterectomy, laparotomy, herniotomy, and ovariotomy operations, in which the peritoneum is so largely involved.

Who can doubt on witnessing the grand results that are obtained every day now, I may say, in abdominal surgery, if I might so call it, that the grim peritoneal spectre, the inability to cope with, and natural dread of which, paralysed the efforts of our surgical predecessors, and consigned so many to the grave, is in a fair way of being banished by the magic wand Antisepticism? Instead of the dreaded apparition, we have presented to us to view with awe and admiration the possibility of such a splendid surgical achievement as that of Keith, namely, an unbroken succession of seventy successful ovariotomies, than which there is not in the annals of surgery a triumph so signal and complete.

◆

## THE PATHOLOGY OF STARVATION.

By Surgeon-Major WM. CURRAN,
Army Medical Department.

"I MYSELF saw strong men and young women die of starvation; one young girl especially, of nineteen, the eldest of a poor family of nine, struggle in the jaws of hunger for six months and then perish, literally reduced to a heap of bones. I did my best at the time to help that family. I was then only eighteen years of age. I saw two men dead with grass in their mouths, having striven in vain to obtain sufficient nutriment to sustain life from the grass of the field. Scenes likes these were then common. Many would not believe that such things occurred, but I saw them. *I saw hundreds of children, from the age of two to twelve, with hair on their skinny arms and cheeks fully one inch long—a false growth caused by decay and hunger.* I saw over one thousand men, women and children of all sizes and ages outside the poorhouse of Castlebar, assembled for inspection by order of the Poor-law guardians, lest any name should be on the relieving officer's list except those who were actually at the time alive. I cannot say in the flesh, for flesh they had none. Their presence at the time, young as I was, reminded me of the vision of bones beheld by the prophet."

Having seen this paragraph in an American paper which was sent me by a friend in that country, and not having noticed anything like the development referred to in italics therein in any of the books or papers bearing on famine that have come under my notice, I am induced to advert to the point here, and ask for such information respecting it as may be at the command of your readers. I will incidentally allude, as I advance, to other incidents of the question, in the hope of thereby eliciting more attention to, or of throwing more light on the subject of starvation generally, than it appears to have hitherto received. Nor is the time or season unsuited for such an inquiry, for famine is again stalking with all its grim and ghastly accessories through extensive portions of our unhappy country, and we may naturally expect, as a consequence, a recurrence of the diseases it usually produces. What these are it behoves us to ascertain, and that, too, in advance, for knowledge is power, and to be warned in time is to be forearmed against the danger, and prepared for the assault. Let it not be said of us, after the event, that

Macies et nova febrium,
Terris incubuit cohors,

the nature of which we did not adequately recognise or understand; and that we were thus taken at a disadvantage, if not actually surprised before the fight. Whether the condition or conditions developed by famine be remediable or not, is for us to determine, and the question has not, so far as I know, been ever raised from this standpoint, up to date, on your side of the Channel. Anyhow, I am not aware of any such *exposé* or analysis, and I am accordingly more a seeker after truth than a diffuser of knowledge or novelty in this, to me, *terra Australis incognita.*

Anxious to ascertain how far the particulars given above, but especially so those underlined, were reliable, I wrote to their learned author, the very Rev. Canon Bourke, of Claremorris, the eminent Keltic scholar, and was assured by him in reply that there were hundreds of such cases among the famine-stricken children of the disastrous period referred to therein. He added that a lad of twelve, whose cheeks were wan as those of a corpse, invested with the cerements of the grave, and who presented all the other usual features of chronic starvation, exhibited this peculiarity in a very striking manner. He compares it to the kind of growth or efflorescence that one finds on fungi or other decaying matter, and he adds that this lad's arms were throughout covered with hair of this downy character. It was equally prominent, though for obvious reasons not so observable in their seniors, and he seems to ascribe it to the exudation or moisture that is produced by dirt and decay. In the letter I did myself the honour of addressing to him on the point, I mentioned that, as far as my experience of such events went, starvation was usually, if not invariably, associated with diarrhœa or dysentery, and I added that their presence was readily accounted for by the fact—recently established by a medical officer (Dr. Cunningham) in connection with the famine in Madras—that the lining membrane of the bowels had undergone a process of fatty change or degeneration. I added that dropsy was also an occasional consequence of this condition, and it is always necessary to bear in mind, in this connection, that to use the painful words of Mr. Mitchell Henry, "in considering the state of Ireland, one must start with the hypothesis that the normal condition of a very large proportion of the people was one of semi-starvation." But whether these are all the disorders that accompany or follow from famine, or whether fever, and if so, what type of fever is necessarily associated with it, I am unable to determine, and this is the reason why I venture to bring the subject under the notice of such of my brethren as, being readers of your journal, may be able to enlighten us anent it.

What, then, are the diseases that generally accompany, or invariably follow, in the wake of famine. To answer this question satisfactorily would require access to books or reports of a special character which are quite beyond my reach. Men in my position can rarely expect to meet such papers: we are necessarily restricted to a few manuals or practical treatises, and the few publications by laymen that do offer are so vague in their terminology as to be all but useless for purposes of classification. They use indiscriminately such (technically speaking) unmeaning phrases as fever, pestilence, plague, disease, the angel of death, &c., &c., and if we try to isolate these, or ascertain their precise meaning, we find ourselves arrested on the very threshold of the inquiry by the fact that the term fever is a generic one, which admits of numerous qualifications or sub-divisions. Thus, to go no farther for the present, fever may be roughly divided into typhus or typhoid, relapsing or remittent, simple continued or cerebro-spinal, inflammatory, traumatic, puerperal, &c., each of which has its own special life-history and initiative, and again, into jail, ship, hulk-fever, the typhus of armies, and the like. So also with the word pestilence, which is even more abused than the other; and it is hard to say what import these writers attach to it, if indeed, they ascribe any at all. Many of them speak promiscuously or synonymously of it—plague, the black death, or the sweating sickness of our forefathers; and this being so, it behoves us to undertake the investigation with the aid of the appliances that modern science has provided, and divest it of the accretions of an incurious or uncritical age. An Irish medical journal is clearly the fitting medium for such a technical search, and I will be only too glad to act as secretary in the case, and prepare for publication in your columns any or such notes as may be sent to me with that view.

We know so little, medically speaking, of the circumstances that underlie the terrible mortality that depopulated Munster, and led some, if we are to believe Spenser, to cannibalism, after the so-called Desmond-rebellion in the reign of Elizabeth, as to be unable to turn them to any account in this connection. A very similar remark will apply to the war of 1641-2, which ended in 1852 with a loss, according to Sir Wm. Petty, as quoted by Mr. Leeky, in his able "History of the Eighteenth Century," vol. ii., pp. 172-3, of 616,000 souls out of a population of 1,466,000 "by the sword, by plague, or by famine artificially produced ;" and as to the famine of 1740-1, during which "the roads were (to use the same great writer's words, ibid., vol. ii., pp. 218-19) spread with dead and dying bodies, mankind the colour of the docks and nettles they fed on" he adds that "the universal scarcity was followed *by fluxes and malignant fevers*, which swept off multitudes of all sorts, so that whole villages were laid waste." The writer quoted by him in this instance maintained that "400,000 persons probably perished at this time through famine or its attendant diseases ;" and another authority of the period asserted that "whole thousands in a barony have perished, some of hunger, and others of disorders occasioned by unnatural, unwholesome, and putrid diet." Coming to a later and more tangible crisis, one that is within the recollection of many of the readers of this Journal, we find a very similar state of things. Mr. Trench estimates "Realities of Irish Life," p. 110, the loss caused by the famine of '47-8 at 500,000—an estimate which is, I believe, rather under than over the mark—and the population was much denser at this time than it was on either of the former occasions. After premising that "the people were not found dead on the roads or in the fields from sudden deprivation of food," he says that "they sank gradually from impure and insufficient diet," and adds that "fever, dysentery, the crowding in the workhouse, or hardship on the relief works, carried thousands to a premature grave." From this short, but suggestive *résumé* two conclusions may, I think, be reasonably drawn—first, that our hapless land affords peculiar opportunities for the prosecution of an inquiry of this kind ; and secondly, that the objects of that inquiry should, to insure accuracy, be defined and agreed upon in advance. For though we may indulge the hope that no such horrible cataclasm as is described above will occur again in our day, yet is this quite possible, and it is always better to prepare for the worst than wait with folded arms for events to develope themselves. *Principiis obsta sero medicina paratur* should be our guide in such a contingency ; and we should never forget that there is a soul of goodness in things evil, or refuse to take counsel from the history, however chequered it may be, of the past.

(*To be continued.*)

# PORTION OF THE VAGINA OF A SHEEP DILATED INTO A CYST-LIKE FORM ; THE DILATED PORTION CONTAINING NUMEROUS BONES AND SOME WOOL. (a)

BY BENJAMIN W. RICHARDSON, L.R.C.S.I.
Surgeon to Adelaide Hospital, Dublin.

THE author said, the specimen, I have the honour to present to the Society, is one of extreme interest, and probably of rarity also ; but not being familiar with the pathology of the sheep I cannot speak with any confidence on this point.

Several days ago on going into my butcher's shop he handed me what at the time appeared to be a cyst he removed from a ewe while dressing it for sale. He showed me the part of the carcase where its upper surface was adherent. This part was situated a little anterior to and above the vaginal orifice at the left side of the spine, assuming the animal to be alive and on its legs. Being inquisitive as to the nature of this bag, as he called it, he made a couple of cuts into it, but on seeing that it was filled with little bones he desisted from further examination, thus enabling me to add a very interesting preparation to the museum of this college.

Mr. Abraham, our curator, very kindly made a most careful examination of the preparation, including its walls and contents, with the following results :—The portion of vagina enlarged is sub-elliptiform in shape, the enlargement being 3¼ inches in length, and the transverse diameter rather more than 1½ inches. The cuts that had been made through the wall exposed a number of bones closely packed together. The general appearance was that of a cyst containing bones, and at one part a small amount of hair.

By a little dissection the vaginal nature of the enlargement became evident ; and on passing a probe it was clear that it was not shut off from the anterior and the posterior parts of the passage.

After removal of the contents the wall presented the following appearances :—The mucous membrane was greatly thickened, and internally showed numerous rugosities, pits, plicæ, and outgrowths, some extending half an inch into the cavity ; and among these some of the bones were jammed and hidden. In the recent state the mucous membrane was soft, and in parts almost gelatinous. At the anterior end of the sac the inward growths are largely developed. The orifice which leads into it at this end (and through which the glass rod is passed) opens into the cavity in the middle of a bi-lipped nipple-like protuberance. Posteriorly the outgrowths pass gradually into the normal plicæ of the vagina, which here shows no particular contraction or occlusion.

The contents consist almost entirely of bones and fragments of bones. At one point a small mass of hair or fine wool is collected together, and principally entangled around one of the bones (a rudimental ilium). One hair when pulled out measured over two inches in length. There is no vestige of any fœtal membranes nor of any surrounding covering other than the vaginal wall.

The number of pieces of bone which can be counted is about 170. The shapes of many of them can be well made out ; and the number of the recognisable ones shows that they appertain to one fœtal sheep. There are thus evident two scapulæ, two ilia, two humeri, two femora, the long metacarpals and metatarsals of the third and fourth digits not yet united together, and several of the cranial elements. The vertebræ are distinct, but the union in each of the three principal ossifications, viz., the "central" and the two "neural" has not yet taken place. A soft white substance more or less connects these vertebræ together, and this is the only evidence of any of the soft parts remaining, not even a trace of cartilage being visible.

Although there was considerable irregularity and confusion in the arrangement and position of the bones, yet as the bulk of the anterior skeletal elements were impacted in front, the probability is that the presentation would have been a "breech."

Such, Mr. President, is the very excellent report of Mr. Abraham on this specimen, a specimen which is interesting not only from its novelty—here at all events—but also from its resemblance in some particulars to a dermoid cyst. I think, sir, we may safely assume that the bones and hair are the remains of a partially aborted fœtal sheep, which, having been impacted in the vagina, disintegration of the soft parts took place, leaving the bones and hair, the only vestiges of its previous existence.

## HOTEL DIEU, PARIS.

### *Case of Calcaneo-cuboid Dislocation.*

Under the care of Professor RICHET.

THE patient from whom the specimens shown were taken was admitted two days before. She had been knocked down by a tram car, and when brought in was unconscious and suffering from many contusions, and two very serious lesions. One was a fracture of the surgical neck of the humerus, with which we are not now concerned. The second, much more rare, was in the right foot. The front of the foot was drawn inwards, and on the dorsal surface was an oblique projection corresponding to the upper extremity of the first metatarsal. This bone was clearly broken, and the projection which we felt was formed by the cuboid dislocated on to the os calcis. The skin at this part was much contused.

---

(a) Read before the Surgical Society of Ireland.

Reduction in these cases as in those of sub-astragaloid dislocation is by no means easy. What prevents reduction is not muscular action, but the locking together of the bones, so that chloroform is of little use in these cases. In this woman, however, we attempted reduction: whilst assistants made strong traction on the foot, I endeavoured to replace the bone. Nothing stirred, although the force I employed was such that I feared to break the skin if I pressed any harder.

The day after this fruitless attempt the woman wanted to rise from bed, but died suddenly. At the autopsy nothing was found to explain such sudden death, but we suspected that she had succumbed to fatty embolism of the lungs, such embolism having been often pointed out as causes of death in cases of serious or multiple fractures. To prove this satisfactorily we shall have to make microscopic examination of the lung tissue, and for this purpose it will have to be treated for some time with osmic acid.

With regard to the specimen itself, we have still some difficulty in deciding on the mechanism of the dislocation. We easily recognise, however, that the cuboid has passed in front of and over the os calcis, and that it is caught by the external apophysis of that bone. It was impossible to replace it on account of the small hook with which it is furnished, and which catches in the apophysis of the os calcis. It would be necessary to obtain detachment to draw the parts asunder at least half a centimetre and this is absolutely impossible in the actual state of torsion of the ligaments. After some days these ligaments lengthen and reduction becomes possible : this happened in a case of Nélaton's, and we might have hoped for it here had not death suddenly supervened.

# Transactions of Societies.

## CLINICAL SOCIETY OF LONDON.

### Friday, March 12.

Dr. E. Headlam Greenhow, President, in the chair.

Mr. Frederic S. Eve on

### A CASE OF IMPACTED FISH-BONE IN THE ŒSOPHAGUS, PENETRATING THE DIAPHRAGM AND PERICARDIUM, AND WOUNDING THE HEART.

A man, æt. 59, while partially intoxicated, eat some fish for supper. The next day he went to the nearest hospital on account of pain in the throat and chest. The house-surgeon passed a dilating horse-hair probang. On leaving the hospital he was extremely faint and ill, and complained of severe pain in his chest. He then took to his bed; the pain in the chest was severe, and he vomited all food. On the third day the pain had slightly diminished. In the evening he got out of bed, stretched himself, and immediately fell back dead. Post-mortem examination.—A lance-shaped fish-bone about two inches long penetrated the anterior surface of the œsophagus about a quarter of an inch above the cardiac orifice, transfixed the diaphragm, and the sharp extremity projected through the posterior portion of the pericardium. The opposed surface of the left ventricle was wounded, but not penetrated. The fish-bone was directed obliquely upwards and forwards. The pericardium was distended with blood-stained serum, and contained some blood clot.

The President communicated notes of a

### CASE OF TYPHOID FEVER WITH ACUTE NEPHRITIS AND PROFUSE HÆMATURIA WITHOUT DROPSY.

A porter, æt. 21, was admitted into the Middlesex Hospital under Dr. Greenhow's care on Nov. 25th, 1879, the fifth day of a fever which set in with considerable severity, the second day of the attack being marked by vomiting, cough, and slight sore throat, and in the night he began to have painful micturition, and noticed that his urine was almost black in colour. On admission, pulse 108; temp. 103·2; urine sp. gr. 1012, of a deep red colour from admixture with blood, containing albumen half, numerous blood globules, blood and epithelial casts. He was very prostrate, and suffered from muscular pains; there was impaired resonance with bronchial breathing, and scanty crepitation at the region of the right lung, but no râles elsewhere. The cardiac second sound was reduplicate, abdomen was tympanitic, and there was tenderness and gurgling in the right iliac fossa. The liver and spleen were not enlarged. There was no diarrhœa nor rose spots. Cold sponging was ordered, and a fluid diet. At 9 p.m. pulse 126, temp. 104·8. The illness ran a rapid course, prostration increased; the pulse-rate ranged between 100 and 130; the temperature 97·0° to 104·8°. Restlessness and delirium, passing towards the close into somnolence, and occasional subsultus in arms and legs were observed. The tongue became dry and fissured. The urine continued to be blood-stained, but the amount of blood and albumen diminished. The abdominal distension persisted, and characteristic diarrhœa appeared on the 27th, continuing till death, which took place on December 8, the 13th day of his illness. The autopsy revealed mitral thickening and enlargement of the heart; marked pulmonary hypostasis. Two or three sloughing ulcers occurred at the lower end of ileum, and are in the healing stage, Peyer's glands and solitary follicles being elsewhere swollen. Liver and spleen greatly swollen and softened. Kidneys weighed 12 and 14 ounces respectively, were intensely engorged; their secreting tubules were filled with swollen granular epithelium, and between the tubules there was small-celled infiltration. Dr. Greenhow remarked that he had not met with a similar instance. Albuminuria, when it occurs, is usually a late event in typhoid fever, according to Liebermeister not until the fever had reached its height, and Murchison says it rarely appears sooner than the third week, and is due either to congestion or to parenchymatous degeneration, not as here to acute nephritis. Dr. Murchison also says that when copious hæmaturia occurs it is generally associated with other hæmorrhages. The only parallel instance to the present case Dr. Greenhow had found on record was a reference by Liebermeister to two cases of uræmia from acute parenchymatous nephritis in the Basle Hospital in 1872, soon after admission, and during the height of an attack of typhoid fever. The most careful inquiry failed to elicit any history of previous disease in the present case; so that it seemed as if the trivial cardiac hypertrophy and mitral thickening were due to the very intense nephritis. The points then of chief interest were—the concurrence of typhoid fever with such intense nephritis; the entire absence of dropsy and the severe and rapid course of the disease.

Dr. Cayley said that during his experience at the London Fever Hospital he had seen only one case in anything similar to that recorded by Dr. Greenhow. In one case of hæmaturia, in which death took place at an early period, post-mortem examination revealed intestinal ulcers, one of which was in a partially healed condition, such as might be found after a relapse following typhoid fever.

The President hoped some future advances in the knowledge of such cases might be made; and commented on the significance of Dr. Cayley's admission that his wide experience had not familiarised him with the conditions described.

Dr. Buzzard brought forward

### A CASE OF RAPID AND ALMOST UNIVERSAL PARALYSIS,

which had terminated in a complete recovery under treatment. The patient was a man, æt. 44, whose illness had commenced with some drawing of the face to the right, followed shortly afterwards by loss of power and sensation in both upper and lower extremities. On admission into the National Hospital for the Paralysed, Queen Square, he was found to be paralysed on both sides of the face, both external recti muscles, and also to a great extent in all four extremities, in the movements of respiration and deglutition, and in the sphincters. There was anæsthesia to touch and pain in the face (especially on the right side), with apparently increased sensibility to heat and cold. Below the middle of each forearm there was almost entire loss of sensibility to touch and pain, whilst heat and cold were distinctly recognised. The sensibility of the trunk was preserved. There was loss of smell and taste on the left side. Electric excitability (by induced currents) was almost absent in the muscles of the face, hands, and lower extremities, and much reduced in the forearms. There was atrophy of the interosseous muscles. Respiration was mainly upper thoracic, the lower part of the chest not expanding, and the movements of the diaphragm being scarcely perceptible. No lesion of the spinal column could be found. The patellar tendon reflex was entirely absent in both knees. Under iodide of potassium at first, and later mercurial inunction, patient began to improve so rapidly that on the next day but one after admission he had regained some power over the external recti muscles, and the sensibility of the face to touch and pain was increased. There was gradual and steady amelioration in all his symptoms, and four months after his admission he returned to his work (tailor's cutting) quite well. The patellar tendon reflex returned about this time in both legs. Twenty years previously to his attack patient had suffered from a chancre, the scar of which remained visible. With the exception of this he declared that he had never had a day's illness. In his remarks Dr. Buzzard compared the case with those first described by Landry, to which the title "acute ascending paralysis" had been given, which were usually fatal, and in which there were no marked post-mortem changes. The present case differed from this type in the extensive affection of sensibility, in the greatly reduced electrical excitability of the muscular system, and in the implication of ocular muscles. It resembled, however, most strikingly a case brought to this Society by the author in 1874, which presented almost precisely similar symptoms, in which, as in this, there was an old history of syphilis, and which recovered under similar treatment in about the same time. A diffuse myelitis involving the cord, the medulla oblongata, and the pons, might give rise to the symptoms. So also perhaps would a lesion of the intra-cranial and spinal membranes with effusion compressing the nerves. Was it possible that there might be some thickening of vessels of the pia mater, an endarteritis of syphilitic origin giving rise to disordered circulation? All the cases that Dr. Buzzard had seen recovered, and he could add nothing positive in reference to the pathology of the disease, which was confessedly obscure.

Dr. Althaus inquired whether an examination had been made of the degree of sensibility retained in the mucous membrane supplied by the fifth cranial nerve?—whether, for instance, it responded to the stimulus of ammonia, or if the tongue, though insensible to sapid substances, would show evidence of pain on irritation? He thought information derived from such tests might assist the localisation of the disease.

Dr. Stephen Mackenzie was of opinion that the muscular atrophy described in Dr. Buzzard's paper might be taken to indicate the existence of a lesion in the spinal cord, and possibly also of the membranes enclosing it. He instanced the case of a young girl who, after severe cephalalgia, fell suddenly, and was conveyed insensible to the London Hospital, where she was discovered to be partially paralysed. She was examined by Drs. Sutton, Hughlings Jackson, and Ramskill. Her sensibility (response to stimuli) was imperfect, and she was so intensely livid as to suggest the probability of mischief being done to the pons. She was bled to 30 ounces, but died 40 hours after admission. No structural change in the nerve centres was discovered post mortem. In a second case, noticed ten years ago, a man was suddenly overcome in a somewhat similar manner, and was attacked with rigid tetanus. He died three days subsequently, and in him likewise no change in the nerve centres could be made out. The cases, Dr. Mackenzie considered, proved that there is an obscure class of diseases about the pathology of which really nothing definite is known. There is the greatest difficulty in diagnosing the lesions producing such extensive changes.

Dr. Mahomed was reminded by Dr. Buzzard's paper of a case he had seen some time ago. It was that of a young man who became suddenly ill, and the subject of intense vertigo. He could not stand, was very sick, suffered severely for a week from headache, and became rapidly paralysed in the lower extremities. His pulse was irregular, and he was much troubled with hiccough. He at first denied any previous syphilitic history, but Dr. Broadbent made out that he had been treated formerly for sore throat, and had been prescribed iodide of potassium and mercury. He could not distinguish heat and cold, and even several weeks after recovery, when in a cold bath, one side of the body was distinctly hotter. His urine was offensive, and evidently passed in a decomposed state. This was probably due to unknown chemical changes of the urea and kreatin. This patient recovered; his disease was of syphilitic origin. Dr. Mahomed wished to know whether the urine passed by Dr. Buzzard's patient was abnormal.

Dr. Buzzard said nothing noticeable had been seen in the conjunctiva in the case he reported. The ammoniacal test was not applied to the Schneiderian membrane; the whole of the fifth pair of nerves were, however, undoubtedly involved in the disease. Dr. Mackenzie had not indicated whether any history of syphilis was recorded in connection with the cases cited by him.

Dr. Mackenzie said no such accounts had been given. The cases occurred ten years ago, and he could not remember all the details of them.

In his own case, Dr. Buzzard continued, no peculiarity had been noticed in the condition of the urine when voided.

The President remarked that four years ago he saw a lady who had lost all power in her four limbs, and whose tongue was also paralysed. These changes succeeded to diphtheria, and were of the most complete character he had witnessed. He was of opinion that Dr. Buzzard's case was a very similar one in the nature of its symptoms, though it was of syphilitic origin.

Mr. Frederic S. Eve communicated

### A CASE OF FRACTURE EXTENDING THROUGH THE TEMPORAL BONE.

A boy, æt. 13 months, fell off a bed and struck his head against a mangle. On admission to St. Bartholomew's Hospital he was insensible, vomited, and there was bleeding from the right ear. The next morning there was a profuse discharge of clear watery fluid from the ear, which continued until he died, on the third day after the accident. Post-mortem examination: Lymph was effused in the subarachnoid space over the whole surface of the brain, but most abundantly over the right hemisphere. A fracture passed vertically through the squamous portion of the temporal bone and the petrous bone, cutting across the external and internal auditory meatuses, and terminated at the foramen lacerum posterius. A coloured injection thrown into the external auditory meatus passed out through the internal meatus, issuing from within the sheath of the nerves, thus demonstrating that the watery discharge in this case was the cerebro-spinal fluid.

Mr. H. Clutton, F.R.C.S., on

### A CASE OF FEMORAL ANEURISM—LIGATURE OF THE EXTERNAL ILIAC ARTERY—CURE.

A patient, æt. 46, was admitted into St. Thomas's Hospital on December 9, 1878, with an aneurism of the right femoral artery, of about the size of a walnut, immediately below Poupart's ligament. It had been noticed three or four months. There was no history of syphilis or injury. There was slight arterial degeneration, but no marked affection of the heart. He was placed under the influence of iodide of potassium, and a restricted diet. Every variety of pressure was tried with the exception of the compression of the abdominal aorta, but they all failed. Under these circumstances the external iliac artery was ligatured antiseptically by Mr. Clutton, on January 11, 1879, with a thoroughly carbolised silk ligature, of which the two ends were cut short. A catgut drain was then inserted, and the wound closed with silver sutures. Pulsation in the tibial arteries returned in three days. As the temperature never rose above normal, and there was no oozing, the dressing was not changed for a week; the wound was then found completely closed; pulsation, however, could be felt in the sac. At the end of another week the dressing was removed for the second time, and the wound found soundly and firmly healed. Pulsation in the aneurism, however, continued till February 15 (five weeks after the operation), when he was suddenly seized with pain in the right groin. Shortly afterwards the aneurism was found quite solid, and never again pulsated. But on February 23, exactly six weeks after the operation, there was slight pain and swelling in the wound, and a few days afterwards a thimbleful of sero-purulent fluid was evacuated from the centre of the cicatrix. This little opening continued to discharge only sufficient fluid to keep a scab of about the size of a split pea adherent to the centre of the scar. In this condition he left the hospital on March 15, with the caution carefully to watch for the little loop of silk. On May 22, four and a-half months after the operation, he came to the Hospital with the silk loop in his hand, and the wound again soundly healed without any scab. Mr. Clutton remarked that, considering the number of silk ligatures which are now often used in a case of ovariotomy in this manner, and the few, if any, that have subsequently appeared by suppuration or otherwise, it did not seem at first sight too much to expect from antiseptics, that the silk might become encapsuled in the tissues around the artery as efficiently as has been the case in the peritoneal cavity. In the case before us, too, the ligature was not placed amongst the muscles of a limb where a certain amount of movement must take place, but in the abdominal cavity; thus differing only from the ligature of the ovarian pedicle in its position with regard to the peritoneum: in the case of the artery the ligature is the subserous tissue, in the case of the ovarian pedicle the ligature is lying on the endothelial surface of the peritoneum. He thought that in this fact was to be found the explanation of this apparent discrepancy.

Mr. Eve said he had examined the pedicle in a case of ovariotomy one year after operation, and found the frayed end of the silk ligature employed ½ inch long. When examined with the microscope, leucocytes were found in numbers, so situate as to encourage the belief that they had been gradually absorbed, the substance of the silk, as it were, feeding on it.

Dr. Barclay referred to the early treatment of aneurism, and urged that experience taught the necessity of plenteous nutriment and rest combined if a good result is to be obtained.

The President said Dr. Barclay had opened up a most important subject. The teachings of Tufnell inculcated the necessity of a restricted diet in the treatment of aneurism. His own experience did not confirm this view, however. He had submitted a patient to it for six months, continuously, in vain. Only the day previously he had seen a case in Middlesex Hospital which had been treated so; it was, and had remained since last November, *in statu quo.*

Dr. Greenhow suggested that on some future occasion Dr. Barclay should bring cases in support of his views before the Society, and open a discussion on the subject.

Mr. Clutton supported the evidence that when examined by the microscope the silk ligatures left in the peritoneum were found fewer in number, and in process of being absorbed. In Prof. Lister's case, however, no absorption occurred, but the silk was disintegrated and distributed in the surrounding tissue. Had the patient lived suppuration must have taken place. In his own case, he added, the silk left *in situ* became the centre of a bad inflammatory action.

◆

## SURGICAL SOCIETY OF IRELAND.

A meeting of the Surgical Society was held on Friday evening, February 27, in the Albert Hall, Royal College of Surgeons, Mr. E. Hamilton, Senior member of the Council of the Society present, in the chair.

Mr. B. Wills Richardson, hon. sec., read the minutes of the previous meeting, which were signed.

### MORBID SPECIMEN—A PARTIALLY ABORTED FŒTAL SHEEP.

Mr. B. Wills Richardson exhibited a dilated vagina of a ewe which contained a partially aborted fœtal sheep, a description of which will be found on page 211.

Mr. Stokes read a communication on

### CASES OF OVARIOTOMY TREATED ANTISEPTICALLY,

which will be found at page 207.

The Chairman said this was the first opportunity the society had had of discussing the subject of antiseptics. He had no objection whatever, and he thought all ought to be of the same mind who had had experience in antisepticism, to express his opinion, which was based simply on his own observation. Many years ago when antisepticism was introduced by Prof. Lister with his putty and tinfoil he was permitted to witness its use through the kindness of Mr. Fleming; and at that time, as occasion arose, he carried out antiseptic surgery in Steevens' Hospital to the best of his ability, and with a good deal of enthusiasm that did not receive the sanction of his colleagues. However, having carried it on for a considerable time his faith began to waver, and he laid it aside as not fulfilling the high character he had heard of it. But, after lapsing into disregard or disbelief of it, his faith was again revived by what he saw in cases of ovariotomy, and he became a perfect convert to antisepticism. To one who had seen surgery in its previous phase, nothing, to his mind, was so marvellous as the utter impunity with which the peritoneum was mopped or sponged and treated in the most extraordinary way, as Prof. Stokes had described. However, it was right to say that his experience in the present session had again shaken his faith in antisepticism; for although he had never carried it out more carefully, and he had been fortunate in having most enthusiastic dressers, he never saw such quantities of matter, in fact, quarts of it. This might have resulted from something in the atmosphere or his application of the method; but he should honestly say that his faith had thereby received another check. In a discussion like the present, he felt it would be a failure of duty if he did not express what had been the bias of his own mind in the matter.

Professor E. H. Bennett said he had brought one branch of the matter before the society three or four years ago—namely, the use of salicylic acid as an antiseptic. It was unfortunate that a second paper which was to follow Mr. Stokes' was not read before the discussion in order to have the set views of another surgeon on the subject.

Mr. Richardson—Mr. Croly has had to leave town.

Mr. Bennett continued that he was under the impression that Mr. Croly's paper would have been read; and so a larger field would be open for discussion. While he entirely approved of Mr. Stokes' paper, he did not think it was a fair view of antiseptic surgery to take it only as relating to ovariotomy; for ovariotomy was very limited, and not within the range of antiseptic surgeons of general practice. However, unquestionably the most important of the whole of antiseptic surgery in reference to ovariotomy was what Mr. Spencer Wells in his last communication on the subject had indicated—an allowance of the antiseptic treatment of the pedicle, so that it may be returned into the abdomen. Mr. Wells had remarked that the success of ovariotomy depended on attention to details; and undoubtedly the same remark might be made in reference to antiseptic surgery in general. In fact, he did not hesitate to say that the failures of antiseptic surgery he had seen in Dublin with his colleagues and elsewhere, were simply due to neglect of that very essential point—attention to details. He had seen it conducted with all the *posse comitatus* of steam engine, carbolic lotion, &c., while the arteries were tied with silk from a roll which the resident pupil took out of his pocket. Again, it was extremely difficult to keep the dirty hands of surgeons—he meant dirty in the sense of not being antiseptically treated—out of the wound, they believing their knowledge something far too fine to enter into such details. He had seen a surgeon dip one finger into a basin of carbolic lotion to save his conscience. In this way details were neglected; and many hospital surgeons would bear him out that what he had stated constantly occurred. Hence, with such treatment they could not expect to have antiseptic operations successfully conducted. With the essential points of Mr. Stokes' paper he entirely agreed. In reference to operations of the general kind apart from ovariotomy—cases of open wound where pre-existing suppuration had occurred—two instances of failure had been mentioned in cases of broken skin and unbroken skin. The unbroken skin cases were due to the cause he had specified, namely, the surgeon's fault in neglecting details. Take that recently brought before the society by Mr. Thornley Stoker—he tied the vagina, but not expecting to deal with this, had adopted no precaution with reference to the vagina itself. In three or four days the wound, although it did not lead to a fatal result, became putrid, the putridity starting from the very pedicle itself; and instantly the ligature was cut through he opened up the source of putrefaction against which he had not guarded. Therefore they must, he submitted, if they had failure, face the question that failure was due to their own fault. He had never himself failed in a fair case whilst the skin was only damaged by a recent wound and no suppuration existed, except where he was able to put his hand down on the actual cause of failure being his own negligence. The view was not to be at all accepted that, although in that respect of immense importance, antiseptic surgery was to be restricted to abdominal section; or to say that it was specially applicable to abdominal section would be to understate its advantages. Any surgeon who would take the trouble to superadd to his breaking of the skin antiseptic measures would be repaid. Even if they wanted to operate against time with reference to abscesses or sinuses, antiseptic treatment would expedite recovery, putting aside all question of risk to life.

Dr. **Doyle** said that in this country they had no data to go on of what was called pure air. As far as theory went, he considered that where there was a concentration of germs the greater the likelihood that putrefaction would supervene in wounds. It would be of great service if any member who had major operations in a mountainous locality away from the city and in a climate free from great variations of temperature, would state his experience, as by that means they would be able to judge whether or not cases under favourable conditions of pure air got on as well as where there was concentration of germs.

Mr. **Wharton** believed operations had been tried in elevated situations, and the air found more or less to cause putrefaction. He understood Mr. Stokes to say the question of antiseptic surgery was by no means settled; and that being so he concurred with Mr. Bennett that the paper was too limited as applying chiefly, at all events, to ovariotomy. There could be no question that the great improvement which had taken place in ovariotomy was entirely due to the principle of Listerism. He thought a great change for the better had taken place in the treatment of wounds consequent on the adoption of Listerism. At the same time, he was not prepared to believe in all that had been said in reference to it. On that, as on other subjects, it appeared to him that something like a medium course would be the one most adapted to bring about favourable results. About six weeks ago he amputated a thigh by the double-flap method, carrying out Listerism as rigidly and fairly as he possibly could. Nothing could do better with regard to the stump for the first fortnight. At the expiration of that time he found that suppuration had become established. Of course at this he was disappointed. However, the quantity of pus manifested by the dressings was very small. Still he was disappointed at seeing pus at all, judging from what he had heard with regard to the treatment of wounds by Listerism. Reflecting on the change it occurred to him that in that particular case Listerism should be abandoned: and he was led to that conclusion by considering that the dressing which had been moistened by means of the carbolic spray would, in fact, act as a poultice and encourage suppuration rather than otherwise. Consequently, he abandoned it altogether and dressed the stump simply with straps of lint, using the ordinary bandage and cold lotion, and nothing could exceed the good results which followed. The patient was enabled to leave the hospital exactly one month after the operation. But he believed had he continued Listerism after suppuration had been established, he would have encouraged suppuration rather than diminished it. Therefore, while Listerism might be carried on with great benefit, a time might come in the management of any case when it ought to be abandoned, at least where such signs of suppuration as those he had described occurred.

Mr. I. K. **Barton** took the liberty of discussing the general question, considering that Mr. Stokes had sufficiently brought it before the society to enable him to do so, and especially as his experience of ovariotomy and the antiseptic treatment was not sufficient to enable him to add much to what had been already said. Having tried it in a great number of cases, his experience in amputation had completely converted him to its inestimable advantages, almost in the exact case just described by Mr. Wharton. In amputations of the thigh the results had been so exceedingly favourable, and very much superior to anything he had achieved before thoroughly antisepticising the wound, he had been converted to accepting the treatment. There had been partial failures—suppuration occurring when he thought he had used every possible means against it; but he was bound to say that, having carefully examined every case that came under his own observation, he was compelled to agree with Prof. Bennett that it was chiefly their own fault. As long as he took the trouble of attending to the details himself the thing went on admirably; but when he left it to his dressers, no matter how earnestly they worked, suppuration became established. The student could not enter into the thorough attention to detail in the same way as the surgeon. He did not think that truth could lie in the golden mean, inasmuch as thorough attention to every detail was absolutely necessary to gain success. The antiseptic method was even in wounds that were freely suppurating or sinuses that had long been suppurating, capable of to a great extent mitigating and in some instances totally checking or stopping suppuration. Within a recent period two cases in point occurred. One was a case of abscess of the breast in a young woman, one abscess forming after another until the whole breast was riddled with sinuses. He slit them open, syringed them, and pursued the usual treatment. At length he resolved to thoroughly antisepticise the tortuous wound and see the effect. He did so, and to his gratification he succeeded in at once changing the whole character of the tortuous, suppurating wound—healthy action set in, the whole thing healed up, and she got perfectly well. Another case was an excision of the shoulder, in which a large abscess extended across the scapula, and another extended down the arm. These had been opened before the operation. There were extensive sinuses across the other scapula, and down to the loins. The operation was done antiseptically, and was but partially successful on account of the wandering sinuses through the back. But the point he wished to notice was that the patient came into hospital on a subsequent occasion with a number of sinuses still remaining, and having put the same practice in operation he succeeded in improving this condition of the sinuses, in which the former treatment had failed. It did not prevent an abscess opening subsequently in front, but it was a small one, and under antiseptic precautions it proved of little consequence, the matter secreted in it having quickly dried up. The salicylic acid recommended by Prof. Bennett was exceedingly useful, and in combination with carbolic acid spray appeared to be the best method of carrying out Listerism.

Mr. **Stokes** disclaimed any intention of wishing to limit the discussion to the subject of ovariotomy, which he looked upon as being, of all surgical procedures, the one that tested antiseptic practice more than any other.

On the motion of Mr. **Thornley Stoker**, seconded by Mr. A. H. **Corley**, the further discussion of the subject was adjourned.

## THE DIGESTIVE FERMENTS AND ARTIFICIAL DIGESTION.—I.

The subject of the digestive ferments and how to use them in artificial digestion has recently been taken up by Dr. Wm. Roberts, F.R.S., of Manchester, in several contributions to contemporary journals. These articles have attracted much attention, and many practitioners are making practical use of the power to artificially digest food. Further, the Lumleian Lectures before the Royal College of Physicians are now being delivered by Dr. Roberts, consequently it may be well to place before our readers the gist of the subject.

The first digestive ferment, ptyalin, is found in the saliva, and converts starch into sugar, until the action is arrested by the acid contents of the stomach. This portion of the digestive action is confined to the conversion of starch into sugar by adding a molecule of water to the starch—a process of hydration, indeed. In the young child, probably, as in the calf, the parotid glands are comparatively undeveloped, while the dietary consists of milk, and the pancreas is the chief agent in digestion. But as the teeth are developed, and starch becomes a large portion of the dietary, then ptyalin is furnished in larger quantities. In many children this salivary ferment is deficient, and consequently they are ill-nourished, and it becomes necessary to artificially aid their starch-digestion. A perfect substitute for the salivary ptyalin is found in the diastase of malted barley. A ferment is chemically a body very much like albuminous bodies, except that it contains no sulphur; consequently a ferment is nutritive itself as well as digestive. Malt, or maltine, is now to be procured in any quantity from a variety of makers, but many of the malt extracts are prepared at too high a temperature to be active. A temperature of 158° F. is fatal to the ferment diastase, and 157° must on no account be exceeded. When added to the material to be digested, diastase is the more active the higher the temperature; but care is to be exercised to see that the temperature does not get beyond 157°. Then, again, diastase, or ptyalin, is destroyed by the acid of the gastric juice; and not a particle in an active state has ever been found beyond the pyloric ring. Consequently, as this is the case, it becomes necessary to add the diastase to starch before it is taken into the mouth. Malt extracts resemble treacle in appearance and in taste; they can thus be added to starch messes before being consumed. Milk containing biscuit powder, or other farinaceous matter, can be warmed, and then the malt extract added, and the whole be put under a "cosey" for a few minutes. There is one practical consideration of importance in this artificial digestion, and that is the temperature. As said before, diastase is killed as regards its digestive power by a temperature of 158° F. To apply a thermometer to ascertain the proper heat is troublesome, and scarcely likely to be properly used by most nursemaids. Consequently some other ruder, but more practically applicable test must be adopted. It is found that when a temperature of 150° F. is reached a fluid becomes too hot to be sipped even. So as long as the fluid can be sipped the temperature for diastase activity is not exceeded. This rough and ready test can always be applied, and as long as the fluid can be sipped the hotter the better, and the more active the ferment. The time during which the farinaceous matter and the diastase should be in contact before the food is given to the infant need not be more than two or three minutes. By such artificial digestion of starch many infants can be well nourished who, without it, waste often to a point incompatible with life.

Then comes the subject of the digestion of the albuminoids of our food in the stomach. The special ferment of the stomach is pepsin, which is active only in the presence of an acid, especially hydrochloric acid. It is active in the presence of other acids, as citric, lactic, or phosphoric, but not to the same extent. The action of pepsin upon albuminoids is to convert them from proteids into peptones by a process of hydration. The albuminoid and gelatigenous portions of our food are digested by a process of hydration, just as starch is changed into sugar by a process of hydration—the addition of a molecule of water. As soon, however, as these peptones reach the blood-current they are de-hydrated back into a proteid (serum-albumen), and this, too, so swiftly that no peptones have been detected in the lacteals or the portal vein. This digestion of albuminoids by pepsin in the presence of an acid can be carried on outside the body as well as in the stomach; the movements of the stomach, however, aiding in the digestion. Pepsin preparations can thus be advantageously given some time after a meal where the digestive powers are impaired. Many practitioners have lost their faith in pepsin preparations in consequence of the preparations being impotent and useless from being badly prepared. But a really active *liquor pepsinæ* will dissolve chopped white of egg rapidly. A teaspoonful in six ounces of water dissolved an ounce of such white of egg completely in three hours. Not only then can pepsin be artificially supplied when the stomach cannot produce it in sufficient quantities, but preparations of meat artificially digested can be procured by those who require them.

So far there is nothing which has not been before the profession for some time, but the researches of Dr. Roberts into the practical use of the pancreatic ferments are very interesting and instructive. Up to a recent period the functions of the pancreas, beyond the emulsionising of fat, were unknown, or but very imperfectly understood; recent investigation, however, has demonstrated that the pancreas plays a most important part in digestion. The pancreatic fluid contains several ferments—(1) a diastase which converts starch into sugar; (2) a ferment which digests albuminoids in an alkaline medium; while it emulsionises fat and has the property of curdling milk, as has the gastric juice. When the contents of the stomach pass the pyloric ring they cease to be acid, and become alkaline. The action of the gastric juice requires the presence of an acid, and consequently is arrested as the food leaves the stomach. We saw before that the salivary diastase is inoperative in the acid stomach, and no diastase in an active state has been found beyond the pyloric ring. When, then, the food becomes alkaline in the duodenum the pancreatic fluid comes into action, and starch digestion recommences, and is completed by the pancreatic diastase. When, too, the albuminoids are passed into the duodenum, then pepsin becomes inert in the presence of an alkali, and the pancreatic ferment, called trypsin, comes into play, and completes the conversion of proteids into peptones. Further, fat is emulsionised, and in this condition is readily taken up by the lacteals. It may be well to follow normal digestion and assimilation a little further, as the reader may not care to look up the subject—perhaps may not have a recent work on physiology at hand. The peptones are absorbed by the capillaries of the gastro-intes[illegible]l mucous membrane, first in the stomach itself, then in the small intestine, and lastly in the cæcal pouch of the large intestine. Sugar is taken up by the venules of the portal circulation, together with some salts. The fat, when emulsionised, is chiefly taken up by the lacteals, but fat is frequently found in the blood-vessels; these lacteals also take up some salts. Such, then, is the process of digestion of our various articles of food in normal digestion.

## A FEW FACTS RESPECTING THE GENERAL MEDICAL COUNCIL AND ITS ADMINISTRATION.

THE Medical Act, introduced in the year 1858 by Mr. Cowper-Temple, which now regulates the registration, examination, and education of the medical profession, sought to effect its purpose by the agency of an elective Council composed of persons elected by the nineteen Licensing bodies of the United Kingdom, together with Crown delegates to represent the State and the public. As this Council is the most important conclave with which professional interests are associated, and as it is likely under, we hope, a reformed constitution, to rule over the medical profession for years to come, it becomes necessary to scrutinise its administration during the past twenty years.

The Medical Act sets forth that the Council shall consist of twenty-four persons—a President elected by the Council—six Crown representatives, four for England, one for Scotland, and one for Ireland, nominated by Her Majesty with advice of the Privy Council, and holding office usually for five years—and one member elected by each of the Licensing bodies throughout the kingdom, save that the Universities of Glasgow and St. Andrews, and those of Edinburgh and Aberdeen are combined for the return of one member for each group.

The meetings of the General Medical Council take place at their Central Offices, 315 Oxford Street, London. They are summoned by the President as often, or as seldom as he pleases. Usually, the Council meets but once in each year, and the time generally selected is within the months of May, June, or July—*i.e.*, after all legislative business of interest to the medical profession has been already disposed of by Parliament. When there has been special business, as in the years 1859, '62, '64, '70, and '78, an additional winter meeting has been held.

During the twenty-one years of its life, we find that the Council has met twenty-nine times, and has occupied 214 days in its deliberations, representing an average of 8·25 days for each meeting; almost the whole of the administrative business of the Council devolves upon the Executive Committee, which meets more frequently and consists of the President, *ex officio*, and four elected members.

The Council comprises three subordinate local branches for the three divisions of the Kingdom, consisting of the representatives for that division, who are in control of the branch office, in which all local registrations are made.

The income of the Council is derived from the fees for registration, payable by duly licensed persons under the 15th section; £2 for each person who held a diploma at the passing of the Act; £5 for each person obtaining one subsequently, and 5s. for each additional diploma subsequently obtained and registered.

Each Branch Council receives the fees from its own division of the kingdom, pays it own expenses, and also a share of the house expenses of the Central Department, and hands over the balance to the General Funds.

In the year 1859 the registration of the medical men in practice at the passing of the Act put the Council in possession of £34,511, as capital upon which to work. The total income which was received from all sources during the twenty years of its existence is set forth in the following table:—

| Date. | Fees. £ | s. | d. | Dividends, &c. £ | s. | d. | Total. £ | s. | d. |
|---|---|---|---|---|---|---|---|---|---|
| 1859 | 34,511 | 10 | 0 | — | | | 34,511 | 10 | 0 |
| 1860 | 3,204 | 10 | 0 | 749 | 11 | 0 | 3,954 | 1 | 0 |
| 1861 | 4,017 | 15 | 0 | 755 | 3 | 7 | 4,772 | 18 | 7 |
| 1862 | 3,787 | 15 | 0 | 768 | 17 | 1 | 4,556 | 12 | 1 |
| 1863 | 4,386 | 15 | 0 | 752 | 19 | 2 | 5,139 | 14 | 2 |
| 1864 | 4,520 | 10 | 0 | 761 | 3 | 9 | 5,281 | 13 | 9 |
| 1865 | 3,614 | 5 | 0 | 787 | 17 | 9 | 4,402 | 2 | 9 |

| 1873 | 4,249 | 0 | 0 | 852 | 10 | 7 | 5,101 | 10 | 7 |
| 1874 | 4,532 | 0 | 0 | 885 | 14 | 3 | 5,417 | 14 | 3 |
| 1875 | 4,718 | 10 | 0 | 882 | 8 | 2 | 5,600 | 18 | 2 |
| 1876 | 5,143 | 0 | 0 | 874 | 13 | 9 | 6,017 | 13 | 9 |
| 1877 | 4,814 | 0 | 0 | 876 | 13 | 8 | 5,690 | 13 | 8 |
| 1878 | 5,058 | 0 | 0 | 863 | 13 | 0 | 6,206 | 13 | 8 |
| 1879 | 5,136 | 0 | 0 | 847 | 5 | 7 | 6,780 | 9 | 11 |
| | 119,665 | 10 | 0 | 16,150 | 10 | 5 | 136,898 | 5 | 4 |

Thus it would appear that the medical profession has been taxed for the maintenance of the Council to the extent of £137,000, or at a rate of over £6,500 a year. In addition to this amount the Council has received for dental registration within the last six months of 1878 and the year 1879 a sum of £12,000, and will be in receipt of a steady future income from this source also. Nevertheless, with this very large aggregate income, the Council is living beyond its means, as the following table will show:—

*Comparative Income and Expenditure of the General and Branch Councils during the last eight years.*

| | 1872. £ | 1873. £ | 1874. £ | 1875. £ | 1876. £ | 1877. £ | 1878. £ | 1879. £ |
|---|---|---|---|---|---|---|---|---|
| Income .. | 6106 | 5338 | 6004 | 5877 | 6286 | 6035 | 6203 | 6780 |
| Expenditure | 3446 | 5125 | 6882 | 6698 | 5911 | 6684 | 6322 | 5420 |
| Excess of Income .. | 2660 | 212 | — | — | 374 | — | — | 1360 |
| Excess of Expenditure .. | — | — | 878 | 820 | — | 649 | 116 | — |

It will be seen that—with the exception of the last one and other year—the Council has for the last six years been drawing steadily upon its capital, although during that period there was no decadence, but rather a steady increase in its income. Its outlay is made up, speaking generally, of—

*a.* Fees to members.

*b.* Printing of Pharmacopœia and Registers.

*c.* Miscellaneous printing.

*d.* Salaries and establishment charges.

The relative expenditure of the last three years, of which accounts have been published, is set forth in abstract in the following table—

*Expenditure of the Council for the years* 1876, 1877, 1878, *and* 1879.

| Expenditure. | 1876. £ | s. | d. | 1877. £ | s. | d. | 1878. £ | s. | d. | 1879. £ | s. | d. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Fees to Members of— | | | | | | | | | | | | |
| General Council ... | 1880 | 11 | 0 | 2139 | 18 | 0 | 2476 | 8 | 0 | 1816 | 2 | 0 |

| Stationery, Postages, &c. | 196 | 12 | 10 | 220 | 5 | 8 | 202 | 17 | 16 | | | |
| Total | 4390 | 2 | 4 | 5205 | 2 | 2 | 4853 | 14 | 6 | 4123 | 7 | 2 |

The remuneration to a member of the General Medical Council, including his travelling and hotel repayments, and his attendance at Branch Councils—judged from the expenditure of the year 1878—is, on an average, per annum, as follows—

1. For a member resident in London—about £80.
2. For a member resident at a distance, including all his expenses—about £160.
3. For a member of the Executive Committee, resident in London—additional, about £30.
4. For the same, resident at a distance—from £60 to £130.

The functions imposed upon the General Medical Council by the Act of 1858, are—

*a.* The registration of qualified practitioners and the publication of the Medical Register—secs. 14 to 17, and 25 to 28.

*b.* The revision of courses of study and examinations necessary to qualification, and the representation of deficiencies to the Privy Council—secs. 18 to 24.

*c.* The purgation of the profession from persons of infamous character—sec. 29.

*d.* The prosecution of unqualified persons who represent themselves as licensed—secs. 40 to 42.

*e.* The publication of a National Pharmacopœia—sec. 5.

How has the Council discharged its duties? Be it remembered that it was endowed with a cash capital of nearly £35,000—a yearly income of about £6,500—official authority—and ample powers to arrive at information upon the matters conversant with its duties and to enforce its behests. It cannot be denied that the result of its twenty years of existence has been sadly disappointing, and that there is but one feeling in the profession as to its proceedings—one of complete dissatisfaction and angry resentment. Two of its five duties—the construction of a Medical Register and the publication of a Pharmacopœia—it has fulfilled with fair success. The Medical Register, in consequence of the omission by practitioners to notify their changes of residence, and want of vigilance on the part of the Registrars, had come to be so choked with errors as to be perfectly useless as evidence either of the existence of the persons whose names appeared therein, of the non-existence of practitioners whose names were omitted, of the qualifications held by those whose names did appear, or of the residences of the registered practitioners, of which it professed to be a reliable record. It is only within the last two years that the voluntary zeal of Mr. Millar, the General Registrar, has removed this opprobrium, and given to the Register a character for reliability which it never previously possessed. The Pharmacopœia has been accepted by the profession as a work of some merit, and sufficient for its purpose, but not markedly superior to former efforts of the same sort or to the works of well-known writers upon materia medica and pharmacy.

The remaining duties of the Council—those for which it was specially constituted and upon which the well-being of the profession and the public depended, it has either neglected altogether or performed in so perfunctory and weak a manner, as to render its discharge of these functions comparatively useless. Charged to enforce the law against unqualified and incompetent practitioners which was confided to it for that purpose, it has persistently and positively refused to do so—has, by that tolerance, taken the quackery under its protection and, in that way, discouraged the efforts of individuals to enforce the law against unlicensed practitioners, thus indirectly encouraging the encroachments of pretenders to medical skill and withholding one of the inducements which lead people to study medicine and seek a legitimate qualification. Its duty of expurgating the Register from the names of convicts and other persons of infamous character, it has fulfilled occasionally. When the existence of the names of such persons upon the Register was brought within its official cognisance the Council took notice of the fact, and in the case of gross offenders, removed the names. But it has never shown its jealousy for the honour and credit of the profession by initiating such proceedings; and at this moment it displays its anxiety to shirk the responsibility of disfranchising medical criminals by seeking, in the Bill now before Parliament, power to retain on the Register the names of convicts or of persons "guilty of infamous conduct in a professional respect," whenever it may seem to the Council that the offence for which a jury convicted and a judge sentenced the culprit is "of a trivial nature," or that it may, at the discretion of the Council, be condoned.

In matters of medical education and examination to which its deliberations have, in the past twenty years, been almost exclusively devoted, the Medical Council has evinced as great a lack of administrative ability and executive force as in its other business, and has achieved as little practical success. Its heritage in the year 1859 was a semi-chaos of pernicious competition amongst licensing bodies, open victimisation of the public by quacks, and a total absence of any sufficient guarantee of the educational competency of the average medical practitioner, and that heritage it leaves to its successor in 1880, but slightly altered in any essential feature. It has "recommended" changes for the better, but, lacking the courage to battle with the vested money interests of individual institutions, has permitted its "recommendations" to be habitually set at nought, and in this, its twenty-second year of life, it continues to permit the sending forth into the legal practice of medicine and surgery persons who have never possessed, even nominally, the social or professional education requisite for such practice. We look back for an abuse which it has remedied, a public or professional grievance which it has redressed, or a tangible benefit which it has given to our profession, and, finding no such outcome of its twenty-two years' work, we marvel that a voice can be raised, even by the Council itself, for its unreformed continuance.

◆

## THE LUNACY LAW AMENDMENT ACT.—II.

To examine the details of a scheme that is vicious as a whole, that totters into ruin at a glance, would be to waste time, so we shall not at present pause to test the value of Mr. Dillwyn's contrivances for the government of the new public asylums, which he proposes to create, but pass to that part of his project on which he doubtless particularly prides himself, and which provides a new authority for the reception of private lunatics into asylums and their detention there. For the order or request of some person which, when supported by a statement of facts and two medical certificates granted under prescribed conditions, now warrants the reception of a lunatic who is not a pauper into a hospital or licensed house, Mr. Dillwyn desires to substitute the order of a justice of the peace, founded on a petition subscribed by a blood relation within two degrees of relationship or a clergyman or relieving officer, with a statement and medical certificates similar to those at present in use. Now the existing form of order or request is confessedly unsatisfactory; there ought certainly to be some definition of the persons who may and who may not sign it; but it may well be questioned whether it is judicious to superimpose upon it a magistrate's order which will convert the removal of an insane person into a quasi-criminal proceeding. The disinclination of the relations of lunatics to resort to asylum treatment, even when that is clearly indicated as necessary, is already well known, and that disinclination will become insurmountable, when an asylum can only be approached through a magisterial inquiry. No doubt this is unreasonable prejudice, but in legislating, we have to keep in view the weaknesses of humanity, as well as its rational strength, and we cannot therefore ignore the fact that fathers will recoil from dragging their insane daughters, husbands their insane wives, before officials who are principally associated in the public mind with petty larcenies, assaults, and drunk and disorderly cases. When a dire disease, involving civil disability, of an hereditary nature, and still regarded as entailing a species of disgrace, visits a household, privacy is intensely desired, and the strongest antipathy felt to any measures savouring of publicity. A magisterial inquiry has this savour, as well as certain criminal associations, and to insist on it therefore as a preliminary to asylum treatment, will simply be to prohibit that treatment in a large number of cases. Should Mr. Dillwyn's plan be accepted by the country in a moment of artificially produced panic about personal liberty, insanity will be concealed to an extent that has not yet been attempted, and many curable cases will be made incurable by being deprived of timely medical aid, while at the same time there will be an enormous multiplication of single cases, that is to say, of patients boarded out in private houses, into which they can be received without any magisterial authority, and where they can be detained, forcibly if need be, without any inconvenient inquiries. The home-treatment of the insane is admirable in several aspects, and many harmless lunatics are excellently accommodated, and enjoy great liberty and comfort as single cases. It is not to be lost sight of, however, that homes for single lunatics are really private asylums on a small scale after all. They are unlicensed houses into which one lunatic is received, whereas private asylums are licensed houses into which any number of lunatics from 2 to 500 are received. But in the unlicensed houses the interference with personal liberty practised and the coercion exercised are often quite as great as in any asylum, and it is to be feared that in them the use of restraint which has been practically abandoned in asylums still lingers. Public officials have pointed out that the liability to abuses in the homes of single cases is much greater than it is in asylums, because they are not subjected to anything like the same amount of inspection, because no records of restraint or seclusion or punishments are kept in them, and because the persons who preside over them, if cruel or capricious, are not kept in check, as asylum proprietors are by their paid officials. What Mr. Dillwyn proposes to do, then, or rather what his Bill will do, whatever his proposals may be, is to abolish a number of large asylums in favour of small ones, and to disperse over the country, in hidden corners, evils which, whatever they may be, are at present concentrated in well-defined places. The magistrate's order will, we believe, like many other specious devices, defeat the ends with which it has been designed, and aggravate the abuses it is intended to cure.

The provision in clause 11 for the annual recertification of lunatics in asylums has, like the magistrate's order, a specious appearance, but a hollow ring when sounded by those who understand the working of all such provisions. Its effect would be to limit to one day in the year, that on which the form in Schedule F is signed, a responsibility which ought to weigh on every medical superintendent perpetually. Each medical man in charge of the insane ought to be able to certify at any moment that the detention of every lunatic under his care is then necessary and proper. To require him to do this once a year is to absolve him from the obligation of doing it oftener, and the result of the clause becoming law would be to destroy the sense of daily answerability. A grand audit would be held once per annum, a holocaust of patients would be recertified without any nice discrimination, and a number of poor wretches would be detained in asylums for an unwarrantable length of time.

The sanction given by Section 12 to the reception of voluntary patients into asylums must be of dubious advantage and limited operation, for voluntary boarders, who are entitled to leave on giving three days' notice, are apt to arrogate to themselves privileges which are inconsistent with good discipline and order, while their presence in an asylum must be a standing irritation to the certified lunatics who have sense enough to understand that they are less fortunately situated, and cannot withdraw from durance when they are tired of it. Such a nuisance, too, many voluntary patients prove themselves, and the directors of one large chartered asylum in Scotland have, we understand, resolved to avail themselves no longer of their power to receive them, and to refuse to admit them on any terms. The voluntary clause would be taken advantage of chiefly by dipsomaniacs, in moments of contrition, and they are not desirable inmates of an asylum, and ought to be provided for elsewhere. Mild cases of insanity, and those in which the disease is in an incipient stage, should not be encouraged to place themselves in the midst of lunatic environment, and facilities need not, therefore, be offered to them to enter asylums when their morbid tendencies are likely to be strengthened. Only in relapsing cases, or in the case of convalescents without homes, is the voluntary clause calculated to be really useful.

◆

## THE MEDICAL REGISTER FOR 1880.

The annual official list of our profession has just appeared, the period of its issue being commendably early in the year, and it bears even on its exterior the signs of progressive improvement and care in its production which make it evident that there exists, at least in the executive department of the Council, an earnest desire for improvement and the necessary energy to carry that desire into effect. The Register has come to be a somewhat corpulent volume, for it contains this year 812 pages as against 675 which it contained in 1879. This increase of its dimensions is due not to an influx of new names, for, in fact, the entries are somewhat fewer than those of last year, but to the rearrangement of the lists so as to make them more readable. Previous editions of the Register were printed, as we have before observed, in a very unworkmanlike style, being almost devoid of margin, and so crushed in, for want of room, in the stitching as to make it difficult to read the first letters of the names and the first words of the lines of the prefixed Acts of Parliament. To remedy this difficulty it became necessary to narrow the page of print a little, which involved in many instances the running of addresses into two or more lines and thus extend the list over a greater number of pages. For the extra expense thus incurred the Council is repaid by having a respectable and creditably printed official list, which it has never had before.

As to the accuracy of the Register, the improvement upon the editions of a few years since is still better marked. Up to 1878, it seems to us that no attempt was made to keep the Register correct. Those medical men whose deaths happened to be notified to the Branch Councils or to come in some way under their notice were struck out, but as these were a very small percentage of those who died, the list became gradually filled with names of persons who had gone over to the majority years before, and thus the roll of the profession appeared much greater than it really was. The errors in addresses accumulated still more rapidly because the profession was constantly in motion and few persons ever gave themselves the trouble of notifying to the branch Registrar their change of residence, and for these causes the Register became so untrustworthy as to be of no value whatever as evidence that a practitioner whose name, address, and qualifications were contained therein, resided at the address given, or was in existence at all, or that he held no other qualifications than those set down against his name. The statistics of Registries given at page 69 in the issue of the Register for 1880 illustrate at once the complete neglect of this part of the Registrar's duty in past years, and the efforts which have been made since Mr. Miller came into office to amend the multitudinous inaccuracies of the book. For instance, we find that in 1877 only 517 names of deceased practitioners were erased, of which only 37 were removed under the section of the Act which imposes upon the registrars the duty of keeping the Register correct. In the year 1878 and '79, as a contrast, we find that 1,310 and 1,109 names respectively were struck out. In other words, in these two years under Mr. Miller's energetic supervision 2,419 names of dead men were elided, of which at least a thousand would still be there if the work of correction had gone on as it did in previous years. But the removal of these 1,000 names of dead men, which of itself must have involved much labour, because of the circumlocutory method which must necessarily be adopted, does not represent a tithe of the work which had to be performed with the object of correcting the addresses of practitioners. From our own experience of the extreme difficulty of inducing medical men to answer a letter, or persuading the postal authorities to return a dead letter, we can fully appreciate the nature of the task undertaken by Mr. Miller, and can give his department full credit for the success achieved. It is a satisfaction seldom allowed to us to speak with unqualified approval of the work done by the Medical Council. We can do so on this occasion, and we hope that the correction of the Register will be followed up with perseverance, so that that volume may yet come to be at least as reliable as either of the Medical Directories.

# Notes on Current Topics.

## The Vacant Irish Poor-law Commissionership.

THE office formerly occupied by Mr. Bellew still remains unfilled, and, we are gratified to report, Mr. George Morris, M.P., has *not* been provided for in the Local Government Board. We hear that the Government has been looking about for a warming-pan to keep the office ready for a supporter. Mr. Sharman Crawford was spoken of for that ephemeral office, and Mr. Andrew Doyle, who acted with Major French as one of the Irish Poor-law and Lunacy Inquiry Commission of last year, has been also named as being likely to hold office in the Department, either permanently or *pro tem.* We believe that he possesses the necessary qualities for a smart, industrious, executive commissioner, but we do not know that he has any claim on this score superior to those of Mr. O'Brien, who served many years as inspector in the Department, and is now Secretary to the Irish General Prisons Board.

We would hope that the danger of a political job at the expense of the Irish pauper is becoming more remote.

## The Next Meeting of the General Medical Council.

THE Executive Committee of the Council meets to-morrow at two o'clock, and no doubt discussion will arise as to the probable date of the meeting of the full Council.

We take the occasion again to protest against the system of dog-day meetings of the Council, at a season which is convenient to none save London consultation practitioners, and which seems to be specially selected by the President in order that the Council may have as little to do as possible, and that it may leave that little to be done by the outside public. It would be interesting to the profession if we could tell them when it is likely that the Council will deal with the question of expurgation of the Dental Register, with the Irish certificate system, with the replies of the licensing bodies to the "recommendations" submitted for their criticism, with preliminary examination and with other subjects which were crushed out of consideration last year by the question of medical reform.

There is good work for a fortnight's sitting ready this moment, and pressing upon the attention of the Council; but we suppose its President will, like a gentleman of our acquaintance who always left his letters to be answered by circumstances, leave these matters to be settled by the ordinary course of events. It seems to be a formally adopted policy of the General Medical Council to "let things slide," as our American cousins would say, and the Council undoubtedly enjoys the services of a President who is thoroughly in accord with such a system.

## The Profession at the Levee.

ON Wednesday last Her Majesty held a Levée in person at Buckingham Palace, when the following members of the profession had the honour of presentation :—Dr. Samuel Wilks, on appointment as Physician-in-Ordinary to their Royal Highnesses the Duke and Duchess of Connaught, by his Royal Highness the Duke of Connaught; Dr. John Watt Reid, on appointment as Director-General of the Medical Department of the Navy, by the Secretary of State; Brigade-Surgeon Kidd, on promotion, by the Adjutant-General; Dr. Wykeham Hawthorn Lydell, Surgeon Central London Rangers, by Major Mark B. F. Miller; Surgeon Saville, North Somerset Yeomanry Cavalry, by Lieutenant-Colonel the Earl of Cork and Orrery.

### Society of Metropolitan Medical Officers of Health of Dublin.

A MEETING of the above society was held at the Royal College of Surgeons in Ireland, on March 10, at 4.30, Surgeon H. G. Croly, and afterwards Dr. Darby of Bray, in the chair. The meeting was numerously attended. The minutes of the previous meeting having been read and signed, Dr. Pollock read his paper on "Compulsory Removal to Hospital of Persons suffering from Infectious Diseases," which was followed by a prolonged discussion in which many members took part, and eventually adjourned for further discussion to the next meeting of the society on April 14.

### The Successor to Dr. O'Leary, M.P., in the Surgeoncy to St. Vincent's Hospital, Dublin.

DR. MATHEW JOSEPH KEHOE has been elected to occupy the hospital surgeoncy vacated by the lamented death of Dr. O'Leary, M.P. Dr. Kehoe is a Licentiate of the Irish Colleges of Physicians and Surgeons, and a Demonstrator in the Catholic University School, and may on some indefinitely future occasion prove himself to be worthy of the responsible charge of an hospital. But as we have recently protested warmly against the appointment of a gentleman of one year's qualification to the care of the medical wards in Dr. Stevens's Hospital, Dublin, we also protest against the transfer of the lives and health of the St. Vincent's patients to a young man of such unproved, but possibly great qualities as Dr. Kehoe. The managers of the hospitals in Dublin may be well assured that the outside public and the executives of charitable organisations in that city will not long continue to submit to the perpetration of jobs of this sort, be they medical jobs, political jobs, religious jobs, or personal jobs, and that if the system be long pursued of placing perfectly untried men in control of the health of the sick poor, to the exclusion of men who are known to be capable and experienced, the public, and we hope the profession, will take the matter up in a way which may not be satisfactory to those who have charge of such institutions.

### Traumatic Achromatopsia.

AT a recent meeting of the Paris Société de Chirurgie a case of traumatic achromatopsia was related. A colonel, æt. 25, was wounded by a ball in the temporal region; he had all the symptoms of a fracture of the cranium, almost complete loss of memory and achromatopsia, which lasted for two years. During this time he could distinguish only white, black, and grey. The faculty of distinguishing colours returned successively after the discharge of small splinters of bone by the primary wound.

### Arterio-venous Aneurism of the Subclavian.

A CASE was recently narrated before the Surgical Society of Paris of a man who was stabbed between the scapula and clavicle. The hæmorrhage which followed was arrested by tamponing the wound, but a large thrombus formed embracing the upper part of the arm, which became cold and incapable of motion; the radial pulse could not be felt at the wrist. After eight days there appeared in the supra-clavicular fossa a humming or buzzing noise, which could be heard easily, and which coincided with the movements of the heart. Compression of the arm was made by wadding and an elastic band, and the swelling of the arm diminished as well as the thrombus, and the pulse at the wrist returned. After some months the aneurismal bruit had almost entirely disappeared, and the circulation in the limb was re-established.

### Medico-Parliamentary Candidates.

AGAIN, at the forthcoming as at past elections, there is a deplorable lack of candidates to represent medical interests in Parliament, a circumstance which we suppose will be taken as confirmatory of "our poor profession." Yet it is doubtful whether this is the actual reason. True, the very great majority in the medical as in other professions are too poor to aspire to Parliamentary honours, and those who have the means are too much engrossed with a lucrative practice to give up money-making for questionable advantages in the political world. We are rather disposed to attribute this reticence to the everywhere observable fact that medical men take an astonishingly little interest in politics, not even caring to come forward as candidates for the colleges at which they were educated and would stand an excellent chance of return. The only exception on the present occasion is that of Mr. Bickersteth, F.R.C.S., of Liverpool, who intends contesting the Universities of Edinburgh and St. Andrew's, and whom we sincerely hope may succeed. He has a strong committee almost entirely composed of medical men, whose influence with their fellow graduates will probably be sufficient for the purpose. England runs but two medical candidates, Sir Trevor Lawrence for mid-Surrey and Dr. Lush for Salisbury. Ireland also runs but two, Dr. Brady for co. Antrim and Dr. Ward for Galway. These four are tried and valuable members, and will no doubt again head the poll in their respective constituencies. Scotland has four candidates, three new ones, in the person of Mr. Bickersteth, before mentioned, Dr. Farquharson, of London, for Aberdeenshire, and Dr. Theodore Byrne for Dumfries, with Dr. Cameron, the present energetic and useful representative for Glasgow. We can only trust that in every instance our brethren will sink party feeling for the good of our common cause, and do their utmost to return the few medical candidates before them at the head of their respective polls.

### Treatment of Nasal Polypi by Acetic Acid.

SOME years ago acetic acid was much employed in abnormal epithelial growths and some cancroid affections. After being almost abandoned in these cases its use has been recently revived by Drs. Caro and Ciccarini, in mucous polypi of the nose (*Le Praticien*). The acetic acid is injected in 4 or 5 drop doses into the substance of the polypus by means of a hypodermic syringe. The injection is made once, rarely twice. The polypus is generally detached in 4 or 5 days, and some disinfectant injected to get rid of the unpleasant smell.

In accordance with this method, Dr. Caro, on August 12th, injected 6 drops of pure acetic acid into a mucous polypus in the left nostril of a man, æt. 60. Four days afterwards the polyp tumbled off. On September 2, a small mass remained on the middle turbinated bone. Four drops were then injected. No disagreeable effect was produced. The smell of the putrefying polyp was corrected by injection of carbolic acid.

### Milk Adulteration by Country Farmers.

THE adulteration prosecutors in England have determined to follow these frauds to their source. A dairy farmer at Glastonbury was recently charged with supplying milk deprived of three-quarters of the cream. This was the first case of the kind. Many dealers who have been fined for selling adulterated milk having declared that they sold it as it was received from the country, the sanitary inspectors of Lambeth recently went to the South-Western Railway at Vauxhall, and took a portion of milk sent by the defendant to a dealer, and it was found to be deprived of nearly three parts of the cream. The defendant admitted that he had taken off a little of the cream; the dealer had not complained. The latter deposed that he had no notice from defendant that the milk had been skimmed; he had expected it to be genuine. The defendant was fined £10, and £1 17s. 6d. costs.

We do not for a moment suppose that the dealer was innocent in this case. Probably he paid only the price of skim milk, and took good care not to ask questions as to its purity.

### Poisoning by Godfrey's Cordial.

TWIN children of six weeks old were last week poisoned at Atherton, in England, by a dose of a teaspoonful each of Godfrey's Cordial, made up by a woman in the neighbourhood, and administered by her direction. This woman pleaded that she and her mother had made and sold this drug for forty years, obtaining the opium openly and regularly from the neighbouring chemists. The coroner "did not think the woman had been guilty of that carelessness which would be called reckless, and advised the jury not to find a verdict of manslaughter."

### Scotch Diffidence.

THE subjoined manifesto has been issued to the profession by Dr. Dougall, one of the candidates for the Chair of *Materia Medica* in the University of Glasgow:—

> "We, the undersigned medical practitioners, have much pleasure in testifying to the high abilities of Dr. John Dougall, presently candidate for the Chair of Materia Medica in Glasgow University. We know him to be a thoroughly scientific physician, an accurate thinker, and a zealous investigator in the domains of Materia Medica and Therapeutics. His numerous published papers, detailing the results of his original inquiries and experimental researches, have already gained him a favourable reputation in the scientific world. Having now lectured during four sessions on Materia Medica in the Glasgow Royal Infirmary School of Medicine, he has already had considerable experience in teaching this important branch of medical education, and has proved himself a thorough, exact, and very successful teacher. We believe that he is eminently fitted to adorn the Chair of Materia Medica in Glasgow University, and that as a writer of widely acknowledged merit, as an able teacher and lecturer, and as a skilled therapeutist, his appointment would not fail to give universal satisfaction."

### Reform of the Navy Medical Service.

FROM time to time we have drawn attention to the inequalities existing in the medical as compared with other departments of Her Majesty's Navy and the causes which have led to the dearth of medical candidates now existing. To remedy these grievances the Government have just appointed a Royal Commission, which may be characterised as fairly representative of this branch of our profession. The names are: Rear-Admiral Hoskins (President), Dr. Reid, Medical Director-General of the Navy, Fleet Surgeon Fegan, M.D., C.B., Royal Marines, Portsmouth; Mr. W. B. Gurdon, C.B., Treasury; Mr. Willis, Deputy Accountant General of the Navy; Staff-Surgeon Woods, M.D., H.M.S. *Osborne;* Surgeon Tyndall, Royal Marine Artillery; with Mr. J. Garnell, senior clerk in the Naval Medical Department, as secretary.

### The Metropolitan Hospital Sunday Fund.

A SPECIAL meeting of the Council of the Hospital Sunday Fund was held at the Mansion House, Thursday week, for the purpose of receiving a deputation from the Royal Hospital for Incurables. The Bishop of London occupied the chair, and the deputation was headed by the treasurer of the Incurables, Mr. Allcroft, M.P., who urged the claims of the institution to participate in the benefits of the Hospital Sunday Fund. He thought it differed materially from the very many similar charities, as those for idiots, the blind, cripples, &c., inasmuch as it relieved general hospitals of some of their incurable and chronic cases. Dr. Stewart denied this altogether, and said that the Incurables had departed from the original intention of the founders, inasmuch as it had become a voting charity; it had therefore to a very great degree forfeited the sympathy of the medical profession. After a full discussion the Council resolved unanimously, that while wishing well to the objects of the Hospital for Incurables, they could not recognise its claims to share in the benefits of the Hospital Sunday Fund, and they considered it most expedient to adhere to the principle that no institution to which admission could only be gained by the labour and expense of canvassing the general body of subscribers, be eligible for grants from the Fund.

### A Museum Conference.

MR. JAMES PATON, of the Kelvingrove Museum, Glasgow suggests, in *Nature*, that it is desirable to hold a conference of curators and other officials engaged in conserving and organising museums and art galleries. The idea is certainly a good one, and worthy of extended support. Not only will it apply to the general collections and curiosity shops that are the wonder and delight of the simple villagers, but equally to the extensive storehouses of scientific objects, many of which are in their present condition mere chaotic aggregations of valuable material. With very few exceptions the collections that are available to the scientific student are badly arranged, ill-assorted, and almost worthless for purposes of research and observation. The greatest benefit may be expected to follow from a conference such as is proposed by Mr. Paton. The exchange and free discussion of ideas relating to arrangement and management, the productive suggestiveness of such friendly exchanges, and the ventilation the meeting would secure for original methods of increasing the usefulness of the many museums scattered throughout the country, will tend in a great degree to increase their productiveness in the future. In most hospitals there exist special museums, all of which would be vastly improved if more real attention were paid to them and to the means they offer for consolidating the information gained from lectures and books. We doubt not the attractiveness of these collections is capable of an almost unlimited extension, and improvement, in this direction may be anticipated to follow if the curators will accept the proposal made by Mr. Paton.

### The Case of Mr. Whiteford.

Mr. Caleb Whiteford, a surgeon, was charged on Thursday last with the forgery of a letter purporting to be from the Under-Secretary of State, and having for its object the staying of the execution of a man condemned for murder. Mr. Whiteford took a peculiar interest in the fate of the convict, and was energetic in his attempts to secure the remission of his sentence, but without avail. The extreme measure to which he is said to have resorted was the result of his excessive anxiety in the matter. The accused was liberated on bail of two sureties.

### Ambulance Lectures.

In connection with the lectures delivered under the direction of the St. John Association, Dr. Lionel A. Weatherly, Surgeon to the 1st Gloucester Artillery Volunteer Corps, has issued a small volume containing the substance of the instruction given by him in his official capacity to the men of his regiment. The little work consists of six lectures, dealing with the structure and elementary physiology of the human body, the course to be pursued in sudden emergencies of accident, &c., and concludes with a valuable epitome of the rules to be observed in applying bandages and in the transport of wounded sick. The information is clearly expressed, and the work will be serviceable as a text book for use in the numerous classes formed under the order of St. John.

### Payment of Medical Officers of Health by Fee.

We find it stated in a medical contemporary that the proposal of the Okehampton Rural Sanitary Authority to remunerate their medical officer of health by fees for being called in "when the authority sees fit," is *receiving no countenance from the Local Government Board for England*, though it is doubtful whether the central office can, in the present state of the law, do anything but protest. We wish we could say as much as this for Ireland, in which paradise of insanitation the Local Government Board encourages the payment of fees for each occasion on which the consulting sanitary officer is called on for his advice. The Irish Local Government Board is only too glad of this or any other expedient for throwing difficulty in the way of sanitation, and, in fact, it took upon itself, with this object, to transform the office of "medical superintendent officer of health," which was created by the Act into that of "consulting sanitary officer," which was a creature of its own invention. One of the grievances of Ireland certainly is, that while the influence of the English Local Government Board is generally exerted to encourage and enforce sanitation, that of its Irish analogue is in the direction of obstruction and discouragement.

### Poisoning by Oleum Phosphoratum.—A Coroner's Summing-up.

An inquest was held last week at Sparkbrook, near Birmingham, on the body of Catherine Forrest, thirty-two years of age, a single woman. The deceased had been suffering from heart disease, and was attended by a surgeon, who prescribed phosphorised cod liver oil, which she obtained from the local chemist. When a second supply was sent for, the chemist's assistant went to Messrs. Southall, Son, and Barclay, but he received from one of their assistants phosphorised oil instead of phosphorised cod liver oil. The bottle was labelled correctly "oleum phosphoratum," but subsequently a capsule label "pure cod liver oil" was attached by the chemist's assistant. Deceased died after taking three doses from the poisonous mixture.

The coroner, in summing up, remarked that there had been gross carelessness, but he reminded the jury that any verdict of a criminal character arrived at by a coroner's jury *would encounter elsewhere violent hostility, and he would not be a party to induce a jury to find such a verdict when he could by any means satisfy himself that justice would be met by a verdict of death from misadventure.*

The jury returned a verdict to this effect; the coroner also, at the request of the jury, censured the two assistants for carelessness.

### Eruptions Caused by Quinine.

In the *Berlin Klin. Wochenschrift*, Professor Kobner has published some remarks on these eruptions, which have often been described by other observers. A man suffering from bronchitis took sulphate of quinine; two hours after he had a violent rigor, a feeling of suffocation, severe headache, nausea, and vomiting; two hours later another short rigor, followed by a burning sensation, at first in the head and then over the whole body. These phenomena commenced about 8 o'clock in the evening. The next morning there was fever, an itching eruption over the whole body, difficulty of swallowing, and dryness of the throat. The eruption was of a deep red tint, disappearing momentarily on pressure. Face swollen, conjunctiva injected, nasal mucous membrane dry. On the thighs, on the extensor surface, a large number of papules the size of a pea; around these papules the skin was healthy. Pulse 108; temperature of the skin elevated; respiration calm; tongue slightly tremulous, moist; posterior wall of pharynx very red and injected; rest of the mouth apparently normal. Urine showed no important alterations. The author first asked himself whether this was not a migratory erysipelas; then rejected this idea for that of scarlatina, which however was inadmissible for reasons which he gives; he therefore concluded he had to deal with an *erythema exsudationum universale ex usu quiniæ*. In a few days the rash became pale and disappeared, and there followed slight desquamation, especially on the head. Previously to this time the patient had had two similar attacks as the result of taking quinine—1·275 grammes during several days in the first case; 150 milligrammes in two doses in the second. The eruption was considered by the physicians attending as scarlatina, and was each time followed by desquamation. Professor Kobner mentions the case of a physician at Breslau, who, having taken several doses of quinine, had an eruption on the face and scrotum, which he thought was erysipelas. Repeated attack convinced him that it was due to quinine.

The author then studies the differential diagnosis between scarlatina and quinine rash. He draws particular attention to the thermometer, and the analysis of the urine, solely with a view of determining the presence of quinine in that secretion. Amongst other remedies capable of causing cutaneous eruptions he mentions strychnia, chloral hydrate, digitalis perhaps (Traube), belladonna, &c. The author explains the quinine rash by saying that it results from the irritant action of the quinine exercised through the medium of the blood, and not by nervous influence. It is impossible to admit the latter, indeed, for agents like quinine, strychnia, chloral, and digitalis, whose effects on the nervous system are so different, could scarcely influence the vaso-motor nervous system in one and the same fashion. We must evidently reckon quinine among those remedies which have the power of producing artificial dermatoses whether employed topically or internally.

---

The 7th inst. was the eighty-eighth anniversary of the birth of Sir Thomas Watson, Bart., M.D., F.R.S.

---

Mr. F. J. Gant, F.R.C.S., author of "The Science and Practice of Surgery," has been elected President of the Medical Society of London.

---

Dr. Wm. Kirkwood and Dr. William Malcolm Grey Maclure, have been gazetted members of the Legislative Council of the Bahama Islands.

---

His Grace the Duke of Marlborough has appointed James F. Duncan, Esq., M.D., a governor of the Royal Hibernian Military School, in the room of the late James Gibson, Esq., Q.C.

---

Dr. W. Donovan, Public Vaccinator of the No. 4 District of the Ashby-de-la-Zouch Union, has been awarded a Government grant of £19 4s. for proficiency in vaccination.

---

The twentieth festival dinner of the Royal Medical Benevolent College will take place at the Langham Hotel, on Wednesday, the 28th of April, when Sir William Jenner will take the chair.

The University Court of the University of Edinburgh will, on the 12th of April, appoint an Examiner on Clinical Surgery, in succession to Mr. Thomas Keith, F.R.C.S. Edin., who has declined re-appointment.

---

Dr. J. T. Banks, late President of the King and Queen's College of Physicians, has been gazetted Physician in Ordinary to Her Majesty in Ireland, in the room of Sir D. Corrigan, Bart., M.D., deceased.

---

Surgeon G. Kirker, M.D., R.N., has just obtained the first prize at the sessional examination at Netley. This is the first occasion of a naval surgeon gaining this honour. Dr. Kirker was attached to the Surgical Aid Society during the Russo-Turkish war.

---

Mr. Bellamy, F.R.C.S., Surgeon to Charing Cross Hospital, has been elected Examiner in Anatomy at the Royal College of Surgeons of England. Mr. McCarthy, F.R.C.S., of the London Hospital, has been elected Examiner in Physiology at the same institution.

---

Dr. Pettenkofer, well known in this country for his researches in contagious diseases, has received the Bavarian Order of the Royal Crown. Dr. Pettenkofer's last work, "On Cholera," was translated by Dr. Whiteside Hime, of Sheffield, and is the latest reliable work on the subject.

---

At a meeting of the London Central Arctic Committee on Saturday, Dr. W. B. Richardson, F.R.S., in the chair, a resolution was passed appointing the month of May, 1881, as the time of sailing of the New British Arctic Expedition for the discovery of the North Pole, and general Arctic exploration.

---

The scheme to bring sea-water to London has been nipped in the bud by the Parliamentary Committee. The Board of Works objected to the interference with the streets, the subsoil in many of them being already crowded with pipes. So the Committee announced that it was not desirable to proceed with the Bill.

---

At the dinner of University College Hospital, London, held on Thursday last, Sir Julian Goldsmid, M.P., presiding, the chairman, in proposing the toast of the evening, spoke especially of the sanitary improvements which had been effected in the institution, and made an earnest appeal for assistance in carrying on its work, the result being an aggregate contribution of upwards of £1,500 in the room.

---

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Bradford 17, Bristol 19, Birmingham 19, Portsmouth 19, Sunderland 20, Brighton 20, Wolverhampton 20, Hull 20, Leeds 21, Norwich 21, Sheffield 21, Salford 22, Leicester 22, Newcastle-upon-Tyne 22, Oldham 22, Manchester 23, London 23, Edinburgh 23, Glasgow 23, Liverpool 25, Nottingham 26, Plymouth 29, and the highest rate 36 in Dublin.

The death-rate last week from the seven principal zymotic diseases in the principal large towns ranged from 0·4 and 0·7 in Portsmouth and Wolverhampton, to 4·9, 5·6, and 9·7 in Hull, Dublin, and Plymouth. Measles showed the largest proportional fatality in Plymouth, Hull, and Nottingham; scarlet fever in Sheffield; and whooping cough in Salford and Plymouth. Small pox caused 8 deaths in London, 4 in Dublin, one in Bristol, but not one in any of the other large towns.

---

In the principal foreign cities the rates of mortality according to the most recent weekly official returns were—in Calcutta 26, Bombay 32, Madras 42; Geneva 34; Brussels 30; Amsterdam 40, Rotterdam 29, The Hague 25; Copenhagen 28; Stockholm 29; Christiania 21; St. Petersburgh 55; Berlin 29, Hamburg 32, Dresden 26, Breslau 31, Munich 33; Vienna 31, Buda-Pesth 35; Rome 57, Naples 56, Turin 38; Alexandria 35; New York 25, Brooklyn 21, Philadelphia 19, and Baltimore 20 per 1,000 of the population. Typhus and typhoid fever caused 99 deaths in St. Petersburgh.

---

In the current number of the *Irish Monthly* is to be found a most interesting memoir of the late Sir Dominic Corrigan, contributed to its pages by Dr. Mapother, the President of the College of Surgeons in Ireland. It is written with reverence and discrimination, and does fitting honour to one so truthfully described by the writer as "the greatest Irishman who ever practised physic." Dr. Mapother had great and constant opportunities of intimately studying the professional character of our illustrious fellow-citizen, and had equally abundant opportunities of knowing what he was in that private, domestic life, where he was simply the idol of all who had the privilege and happiness of being admitted within the range of its charm and its genial influences.

◆

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**Aberdeen University.**—At a meeting of the Senatus of this University, held on the 6th inst., the arrangements made by the subscribers to the fund in memory of the late Surgeon-Major Shepherd, killed at Isandula, by which a medal is to be awarded to the student who shall make the best appearance in the principles and practice of surgery, were approved of, and the medal will be awarded this session for the first time, the date to be afterwards fixed by the Medical Faculty.

**Glasgow Ophthalmic Institution.**—The 11th annual general meeting of the donors and subscribers to the Glasgow Ophthalmic Institution was held in the Religious Institution Rooms on the 8th inst. The usual characteristic feature of this meeting—inordinate puffing of officials—was duly maintained.

**Edinburgh University Court.**—At a meeting of the Edinburgh University Court, held on the 8th inst., *inter alia*, the following gentlemen were recognised as teachers of medicine whose courses of instruction should qualify for graduation in Medicine in the University, in terms of Ordinance No. 8, viz.:—William Thomas, M.B., and Dr. Jolly, as joint Lecturers on Anatomy, Queen's College, Birmingham; T. W. Drinkwater, Lecturer on Chemistry, Edinburgh; Dr. Alexander James, Lecturer on Institutes of Medicine, Edinburgh; and Mr. A. M. MacAlpine, Lecturer on Botany, Edinburgh.

**Registrar-General's Returns.**—According to the weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending with Saturday, the 6th inst., the death-rate was 24·4 per 1,000 of estimated population. This rate is 2·4 above that for the corresponding week of last year, and 2·3 above that for the previous week of the present year. The lowest mortality was recorded in Greenock, viz., 19·0 per 1,000, and the highest in Paisley, viz., 38·2 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·2 per 1,000, a slight increase in the rate for last week. The number of fatal cases of whooping-cough was considerably less than during the previous week, while an increase occurred in the number of deaths from measles, 20 of which occurred in Dundee. The number of deaths from inflammatory diseases of the lungs was 161, or 18 more than during the previous week. A very considerable increase in the number of deaths from this class of diseases occurred in Dundee. Of the deaths from violence, 5 resulted from a boiler explosion in Glasgow and 1 from the accident to the Tay Bridge.

**Glasgow Public Dispensary.**—The first annual report of this institution, conducted on provident principles, has just been issued. It states "that the dispensary was established to test the acceptability of an institution embodying provident features to the poor of the city not in receipt of parochial relief, and otherwise unable to obtain gratuitous advice, and if need be, medicine also. . . . Necessitous persons receive gratuitous medical advice at the Glasgow Public Dispensary from practitioners who have devoted special attention to certain departments of medical science, and in exceptional circumstances, also gratuitously, the remedies prescribed." It is intended that patients unable to come to the dispensary be visited at their own houses by students, under the supervision of the medical officers. Since its institution this dispensary has done much good; its features are commendable, and it is well entitled to the liberal support of the public.

**The Ferguson Eye Bequest, Greenock.**—The trustees of this bequest have advertised for an oculist in terms of their deed. The person to be appointed must be a competent and experienced oculist, who has made the human eye his study. The duties will be to give advice daily (Sundays excepted) to the outdoor patients at the Greenock Infirmary, and to take full charge of the ophthalmic wards.

# Literature.

## AGNEW'S PRINCIPLES AND PRACTICE OF SURGERY. (*a*)

The first volume of this work has recently appeared containing more than a thousand pages of closely printed matter. This is of a kind which both in quality and appearance will commend itself at once to the reader. It is printed in a clear and excellently defined type, the labour of reading—always a heavy matter in a technical work—being thereby reduced to a minimum, while at the same time it adds considerably to the interest with which the pages are perused. The work commences with an

---

(*a*) Agnew's "Principles and Practice of Surgery." Two vols. Philadelphia and London; J. B. Lippincott & Co.

introduction on surgical diagnosis, this being succeeded by a chapter on the pathology and history of inflammation and its results. The directions and hints offered for the guidance of the surgeon in his determination of the nature of injuries, and the treatment requisite to them, with which the author opens his work, are likely to be of essential service to the young practitioner whose ideas on these points are not always directed in the most brilliant fashion in medical schools. Dr. Agnew's method of procedure is plain and practical, but throughout is guided by the ever present consideration of functional and pathological changes.

The discussion of the pathology and history of inflammation and its consequences is an ably constructed epitome, but less unqualified praise can be given to it than to many other parts of the work.

Chapter iii. includes all injuries of the head. It is well written and instructive, particular points being illustrated by selected reports of cases from British and other hospital records; all the morbid appearances are carefully described, and useful hints are given to assist in diagnosis and prognosis.

Especial commendation must be bestowed on the sections treating of surgical dressings, and the methods of bandaging. With a number of useful works particularly dealing with these subjects, it had been difficult to produce anything superior to them in the way of originality. But Dr. Agnew may be honestly congratulated on having made this, probably the most directly practical part of his book, or at any rate the part most likely to be widely influential, a very perfect and accurate guide for general use. It cannot be too strongly, or too often insisted on, that a surgeon's success is materially dependent on the facility he exhibits with operations of dressing and bandaging wounds and fractures; and it is a considerable source of satisfaction that in an important work like the subject of our notice, full prominence is given to this fact in the care and minuteness with which this particular branch of practice is treated in its pages.

The chapter on ligation of arteries includes the surgical anatomy of the vessels, illustrated by very perfect illustrations of dissections and of the several operations. A noticeable and valuable feature is the presentment in tabular array of carefully collected and numerous statistical returns. These deal with the more important operations for ligature, and in connection with ununited fractures, upwards of seven hundred cases are individually referred to, with the operation performed and result, time occupied in treatment, &c. The value of statistics in proving the desirability of any particular method of operation is open to much doubt; but notwithstanding, those cases are likely to prove of assistance to anyone who will care to consider them in the connection they rightly occupy; not, *i.e.*, to prove the desirability of operating in any individual case, but as enabling the judgment to be directed more particularly to the solution of difficult problems as they arise through the assistance derived from generalised and systematised experience. The tables serve, moreover, as a historical record that possesses no inconsiderable interest, and as such will be acceptable to the reader.

The number of works on systematic surgery recently published in this country and in America is so great, and their style and description so complete and excellent, that it is scarcely to be expected the work now under consideration can be any great advance on several others we mightname. Agnew's "Surgery" will, however, be considered one of the best if the volumes to follow are as good as that now before us.

◆

## THE O'LEARY FUND.

THE lamented death of the late William H. O'Leary, F.R.C.S., M.P., has left his large and helpless family in a position which calls for the sympathy and aid both of the profession and of the public. In the receipt of a splendid professional income, he had just taken and fitted up elegantly the well-known residence of the late Sir William Wilde, in Merrion Square; and had incurred great expense in otherwise providing the *entourage* necessary to his position. As a result his wife and nine young children would be in a state of actual destitution but for the appeal initiated on their behalf by Dr. Lyons; and we are glad to find that that appeal is being nobly responded to, and that some of the Metropolitan Hospitals and Medical Schools have undertaken to give gratuitous education to some of his children when they arrive at a proper age. Additional subscriptions, however, are urgently needed; and will be received by George Sampson, Esq., J.P., Rev. M. F. Shinnors, O.M.I., and Dr. Lyons, 8 Merrion Square West.

# Correspondence.

## PRISON SURGEONS AS WITNESSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 3rd March you make some severe observations on prison officials generally, hinting that their evidence at inquests on prisoners executed in prisons would be more or less tainted, and you give a rather curious reason, viz., that they view things through official spectacles, which have a curious habit of growing dim. If their evidence was perverted by looking through official spectacles, one would reasonably suppose that when such spectacles became dim their normal sight as honourable men would be restored, and that therefore their evidence would be believed. But the imputation cast on the general body of honourable men who compose the prison officials is slight and trivial indeed compared with that you put on the prison surgeons.

You suggest an independant medical man to be chosen by the coroner to witness the execution post-mortem; you state the jury would then have unimpeachable evidence as to whether the execution was conducted in a humane and scientific manner and as to the immediate cause of death. You kindly suggest that the evidence of the prison surgeon might be heard, but you practically state that it is of little or no value because he receives a salary from Government, and you impute that the prison surgeon is not of good standing nor worthy of credit, and that the Prison Department would use its influence to compel him to give false or biassed evidence, and that he would be capable of so doing.

Such imputations against as honourable, independent, and straightforward men as are to be found in the profession ought not to be made without the strongest and most ample proof, and I fearlessly challenge you to produce a single instance in which a prison surgeon has been induced to give biassed evidence. They are incapable of doing so. The Prisons Department would never think of even hinting that such a thing should be done, and if it did so, no surgeon for the sake of the trifling salary he receives, would be so false to his own honour and of that of the profession to which he belongs as to yield to such pressure.

If you had taken the trouble to find out the law with regard to executions before writing such an article, and casting an unmerited slur on your profession, you would have seen that your remarks as to prison officials were beside the question.

The prison authorities have nothing whatever to do with executions, they are simply bound to keep the prisoner in safe custody, to afford a place for execution, and for the burial of the body afterwards.

The entire responsibility of and control over the execution is vested in the sheriff, who has no connection whatever with the prison or its staff. He it is who must erect the gallows and scaffold, who engages the executioner, and sees everything carried into effect. On the day of execution he delivers the death warrant to the governor, and demands the body of the prisoner, who passes from the custody of the prison officials to that of the sheriff, their entire responsibility ceases, and they become and are independent witnesses forced to be present at a most trying and revolting scene, over which they have no control and with which they dare not interfere. Why should they give false testimony to shield defects in the management of the sheriff (if any exist)? Why should they for the sake of an officer in no way connected with their department and for whose acts they have no responsibility, see through official spectacles? And above all, I see no earthly reason why the prison surgeon should so degrade himself as to pervert evidence and give a false cause of death, nor why the Prisons Board should endeavour to induce him to do so for the sake of a functionary over whose action they have no control. If it were not insulting to all concerned, from the Board to the prison warder, the entire thing would be absurd.

I have the honour to be, Sir,
Your obedient servant,
R. J. Kinkead,
Surgeon to Her Majesty's Prison, Galway.

We must decline to allow our observations to be interpreted in any sense discourteous to prison surgeons, respecting whom as honourable men, we specially stated we had no doubt or depreciation to express. We insisted, and still insist, that no prison or other institution in which personal restraint is a part of the system, should be left to the sole control and supervision of the paid officers of such institution, be they medical or administrative officers; and we do not think it fair to distort our words into a slight to those officers because we have said and continue to say that their official relations to the institution disqualify them from being the sole guardians of the rights of liberty within them. Suppose we have the most unbounded confidence in the integrity, courage, and watchfulness of each and every prison officer, we confess we have no such confidence in the departments which have those officers under foot; and we know well that there are often in control of such departments autocrats who would crush without mercy a prison surgeon or other official who presumed to see or to declare publicly the practice of inhumanity to prisoners, whether from bungling or intention. We have in mind the case of Dr. Robert Macdonnell, who was first snubbed, and then practically dismissed from his office in Mountjoy Prison, because he would not agree with his superiors in putting a sick prisoner upon punishment diet, and as we know that there are but very few prison surgeons who could afford to be as independent as Dr. MacDonnell, we do not think it fair to them or safe for the public to throw upon them the sole responsibility of reporting inhumanity at executions.

## Obituary.

### JOHN LEEPER, M.D., J.P.

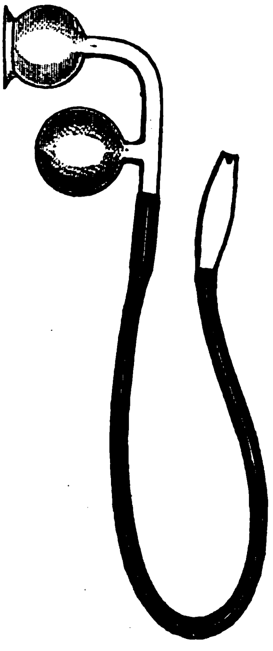
We regret to have to report the death of Dr. John Leeper, from disease of the heart, aged 69. Dr. John Leeper was for some years Surgeon to the Clogher Workhouse, and for the past 35 years was Medical Officer of the Keady District in the Armagh Union. There is no doubt but that his disease was brought on by the hard work, extending over so many years, in attending one of the largest districts in Ireland, comprising an area of 36,000 acres, and his death hastened by continuing to discharge the arduous duties when the disease had made an inroad on his health such as would have driven most men to seek superannuation several years before. He was a man remarkable for the most conscientious discharge of public duty, and had to the last great sympathy with the sick and the poor. He was much esteemed by all classes, and has died amid the universal regrets of the whole community, leaving behind him a name for the strictest integrity, unbounded kindness, and moral worth, qualities which would have adorned any position. The Poor-law Service has lost in him one of their very best officers, and the neighbourhood in which he lived a sound, able, and skilful physician.

### JOHN AITKEN, M.D.

Dr. John Aitken, of Govan, died on the 11th inst., at his residence, Albert Cottage, Govan. The event excited feelings of regret among the entire community of Govan. The deceased gentleman had been in indifferent health for some time past, but recently he suffered severely from inflammation of the lungs, to which he succumbed. Dr. Aitken was 44 years of age, was born in Govan, and had been in practice for over twenty years in his native town. He occupied the position of police surgeon, and a few years ago was presented by the inhabitants of Govan with a horse and brougham. He was of a quiet, unassuming disposition, and his gentle and kindly manners won for him many friends. He was held in high esteem by his professional brethren. He leaves behind him a widow and young family.

## Novelties.

### SUCTION INSTRUMENT FOR POISONED WOUNDS.



The value of suction in removing poison from wounds cannot be denied, provided the suction can be resorted to timely and effectively. Whether the poison be that of the snake or other venomous reptile, the saliva of the rabid dog, the blood or other matter of anthrax-stricken animals, the dangerous material of putrescent organic matter, or any other virulent or septic stuff which has been suddenly introduced by a wound, suction is a ready means of removing it, and thus averting dangerous consequences. But direct suction, by means of the mouth and lips, may sometimes be attended with danger to the operator, and is not always easy or willingly performed. Of course, when it comes to saving the life of a person, or even sparing them mental anguish or physical pain, very few, we fancy, will hesitate in applying their lips and sucking with all their might in order to withdraw the deleterious matter. But, nevertheless, the repugnance does exist, and it is to overcome this, and also to prevent danger to the person who sucks, that Dr. Dolan, whose name is so favourably known in connection with hydrophobia, has devised a little instrument which, if it be at hand when wanted, ought to be most useful. It is something like the pump used for emptying the female breast, but is very much smaller. It consists of a glass tube provided with two bulbs, one of which, at the end, is open, and is to be applied closely over the wound. Into this the blood and poisonous matters are first drawn by means of the india-rubber tubing and ivory mouth-piece, and subsequently into the second bulb which depends from the glass tube, and in this it remains; so that there is no danger of the lips being soiled. Suction, to be successful, should be resorted to without delay, and it is to be feared that this little instrument would not often be at hand at the right moment. Nevertheless, there it is, and even if some delay should occur in applying it, it still comes in useful in washing and cleansing the wound, prior to employing other means of prevention. We have not been able to test by actual practice what appears to be good in theory, but we hope some of our readers will try the instrument, which might also be found useful in other respects.

**Indian Medical Service.**—The following is a list of successful candidates for H.M. Indian Medical Service, who passed on the 8th inst. :—

| | | Marks. | | | Marks. |
|---|---|---|---|---|---|
| 1. | G. W. P. Dennys | 4,964 | 9. | A. C. Thompson | 4,368 |
| 2. | J. W. W. Macnamara | 4,920 | 10. | F. Burness | 4,326 |
| 3. | H. O. Stuart | 4,768 | 11. | G. J. Ward | 4,294 |
| 4. | J. C. Marsden | 4,552 | 12. | F. C. Reeves | 4,153 |
| 5. | J. Sykes | 4,503 | 13. | J. L Poynder | 4,012 |
| 6. | J. M. D. Stewart | 4,450 | 14. | J. Hoey | 3,831 |
| 7. | J. F. Tuohy | 4 393 | 15. | A. G. Collington | 3,755 |
| 8. | A. R. Campbell | 4,375 | 16. | C. A. Daubney | 3,628 |

◆

## NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

☞ Subscriptions.—The Publishers respectfully remind Subscribers that subscriptions for the past year are now due, and should be remitted for England and Colonies to the London office, for Ireland to the Dublin office, and for Scotland to the Edinburgh office.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

A New Colouring Matter.—Specifications have just been taken out at the Patent Office for a new colouring matter for soft tissues or other preparations by a Mr. H. H. Lake. This novelty is obtained by the "oxidation of the sulpho-acid of 'Tetramethyldiamidotriphenylmethine !'" Enthusiastic microscopists, histologists, and others should be careful of their pronunciation when asking for it, or they may have an explosive given to them in lieu of the genuine article.

Midwifery Qualification for the Irish Poor-law.—"A Candidate" asks, Is the diploma of the Coombe Hospital, in conjunction with that of the College of Surgeons and College of Physicians, sufficient for an appointment as dispensary doctor under the L. G. B.

[Yes, the Midwifery diplomas of both Rotundo and Coombe Hospitals are recognised.—Ed.]

Dr. Harbinson.—Communication "On the Peripheral Nerves in Chronic Lead Poisoning" received ; is marked for early insertion.

Dr. Jackson.—Papers "On Sleep and Dreams" accepted, but in consequence of their length we shall be unable to accord them space for at least three months.

### ARMY MEDICAL SCHOOL SELECTION.

*To the Editor of the* Medical Press and Circular.

Sir,—Would you kindly inform me through the *Medical Press* if the Secretary of State has (under the provisions of the late Warrant) as yet appointed any of the Dublin Schools to nominate surgeons for the Army Medical Department, and if not, whether he is likely to do so this year? Yours faithfully,

L.R.C.S.I.

[The Secretary of State has not done so, and it is quite improbable that he will do so as long as a sufficiency of candidates present themselves for the usual competitives. When the supply falls short the selective system may be adopted ; but we hope it may have been abandoned before then, as we regard it as a stupid and pernicious proposal.—Ed.]

The Stomach Speculum.—A skilful physician says that a few days since he was examining a female patient with the speculum. The examination being over, he was about to withdraw the instrument, when he felt himself touched lightly on the shoulder. "Excuse me, doctor," said the patient, "but I have for a long time had a great deal of pain in the stomach. While you are *there* would you kindly tell me what's the matter there?"

A Graduate.—At present but one medical candidate is announced for any of the Universities—viz., Mr. Bickersteth for Edinburgh. You will find a list of medical candidates for other constituencies in another column.

Liverpool.—You will probably find the lamels manufactured by Messrs. Savory & Moore the most reliable and convenient form for administration of the drug.

Dr. W. C. will find his suggestion has been adopted in another column.

Dr. Leatham's paper "On Subcutaneous Emphysema during Parturition" shall appear shortly.

Our attention is called to the following gem of polite literature culled from a Monaghan paper :—

DR. JOSEPH LANGAN,
Catholic University, Dublin ; and Licentiate, Royal College of Surgeons,
Ireland ; Licentiate, King and Queen's College of Physicians, Ireland ; Licentiate, Midwifery,
King and Queen's College
of Physicians,
Ireland.

Begs to advise the Public that he has resolved to select Monaghan as the field of his future professional practice.

Address, till further notice, Currin's Hotel, Monaghan, Feb. 19, 1880.

We hope this gentleman's University and Colleges will be over-elated by the honourable publicity which their *alumnus* affords them. No doubt they will be as proud to claim him as we are to greet him as a professional brother. He might, we think, improve on the advertisement by giving a sketch of his pedigree and a scale of fees.

Clinical Society of London.—Friday, March 19, Mr. Thomas Smith, 1. "Spontaneous Gangrene of the Thumb and Fingers of the Right Hand." 2. "Two Cases of Cystic Hygroma."—Dr. de Havilland Hall, "A Case of Intra-thoracic Sarcoma."—Mr. Nettleship, "Two Cases of Sympathetic Ophthalmitis setting in three weeks after Excision of the other Eye."—Dr. F. Taylor will show a Case of Unusual Transmission of Cardiac Bruit by the Lung.

◆

### VACANCIES.

Birmingham Children's Hospital.—Dispenser. Salary commencing at £80. Applications to the Secretary on or before Mach 20.

Devonport, Royal Albert Hospital.—Assistant Resident Surgeon. Board, but no salary is offered. Applications to the Secretary.

Edinburgh University.—Examinership in Clinical Surgery. Applications to the Secretary before April 5.

French Hospital, Leicester Place, London.—Resident Medical Officer. Must speak French. Salary, £60, with board. Immediate application to the Secretary.

Great Northern Hospital, London.—Physician for Out-patients. Honorary. Applications to the Secretary before March 31.

Liverpool, Toxteth Park Workhouse Infirmary.—Assistant Medical Officer. Salary, £100, with board. Applications, endorsed "Assistant Medical Officer," before March 24.

◆

### APPOINTMENTS.

Abbott, R. T., M.D., L.R.C.S.I., Medical Officer to the Bray Dispensary, Rathdown Union.

Banks, J. T., M.D., F.K.Q.C.P., Physician-in-Ordinary to the Queen in Ireland.

Buckle, J., M.R.C.S.E., Resident Medical Officer to the Western Branch of the Brighton and Hove Dispensary.

Gill, J., M.D., L.R.C.P., Physician to the Stratford-on-Avon Infirmary.

Kehoe, M. J., L.R.C.S.I., L.K.Q.C.P., Surgeon to St. Vincent's Hospital.

Murphy, J., M.D., B.A., Surgeon to the Sunderland Hospital for Women and Children.

Savile, R., M.D., M.R.C.S.E., Medical Officer for the Naferton District of the Driffield Union.

Simpson, W. S., L.R.C.P.Ed., L.R.C.S.E., Medical Officer to the Workhouse of the Pontefract Union.

Story, Mr., an Examiner in Ophthalmic Surgery in Trinity College, Dublin.

Walmsley, F. H., M.D-, M.R.C.S.E., an Assistant Medical Officer to the Leavesden Asylum for Imbeciles.

Woodward, G., M.D., M.K.Q.C.P.I., F.R.C.S.I., Medical Officer for the First District of the Ware Union.

Army Medical Department.—Surgeon Major D. C. McFall has retired on half-pay ; Surgeon Major J. D. Sainter has retired on half-pay.

Navy Medical Service.—The undermentioned Fleet Surgeons have been promoted to the rank of Deputy Inspectors General of Hospitals and Fleets in her Majesty's Fleet, with seniority as stated against their names :—J. Cotton, M.D., Feb. 26, 1880 ; J. N. Dick, Feb. 26, 1880.

The undermentioned have been entered as Surgeons in her Majesty's Fleet, with seniority of Oct. 1, 1879 :—G. Kirker, M.D. ; T. D. Gimlette ; W. Tait, M.B. ; J. Crowley, M.D. ; G. H. S. J. Bankier, M.D. ; J. A. McMann, B.A., M.B. ; J. Brunt, and M. M. R. Mackenzie.

◆

## Births.

Ridley.—March 7, at Moore Hall, Tullamore, the wife of James Ridley, Esq., of a son.

## Deaths.

Bramwell.—Feb. 26, at Nottingham, Charles Crighton Bramwell, M.D., in his 53rd year.

Cornish.—March 7, at Taunton, Jane, the wife of Charles H. Cornish, F.R.C.S., Mayor of Taunton, aged 67.

Drapes.—March 9, at Keadue, co. Roscommon, after a few days' illness, John Benward Drapes, M.B., M.Ch., A.B., T.C.D., Medical Officer of Keadue Dispensary.

Leeper.—At Keady, co. Armagh, John Leeper, M.R.C.S.E.

Richardson.—Feb. 28, at Baker Street, Portman Square, Mark Richardson, M.D., late of the Bengal Medical Service, in his 75th year.

### THE PATHOLOGY OF STARVATION.

By Surgeon-Major WM. CURRAN,
Army Medical Department.

*(Concluded from page 211)*

Looking to India, where a famine of great severity has recently raged, whose effects have been in part, at least, scientifically studied, what do we find? We find that no special form of fever is there generated by want, but that diarrhœa or dysentery is a common, if not an invariable, accompaniment of that condition, and that this diarrhœa can be clearly distinguished from cholera. As these statements are based in some measure on Dr. Cunningham's Report on the famine fever and diarrhœa observed by him at Madras, and as this document is not likely to come under the notice of the readers of this journal, I submit it *in extenso* in the hope that its importance and relevancy to the issue contemplated within will insure its insertion. He has, I understand, discussed the histological elements of the subject in a recent number of the *Quarterly Journal of Microscopical Science.*

"1. I have the honour to report that, in accordance with your instructions, I proceeded to Madras in order to ascertain whether any peculiar forms of fever were present among the inmates of the relief camps there, and to investigate the pathology of the so-called 'famine diarrhœa,' and 'famine dysentery.' I arrived in Madras on the 20th of May, and left on the 8th June, reaching Calcutta on the the 13th of the month.

"2. In regard to the occurrence of any peculiar form of fever, careful inquiries were made as to the presence, then or at any previous period during the prevalence of the famine, of any forms of fever which could in any way be ascribed to the influence of want. I could hear of no such disease as having occurred previously, and during the whole period of my stay at Madras, fevers of any kind were practically non-existent, hardly a case being in any of the hospitals or relief camps in spite of the high degree of mortality prevalent at that time among the inmates of the latter.

"3. I had, however, ample opportunity of investigating the diarrhœa and dysentery so prevalent and fatal in the camps. Careful post-mortem examinations were made of the bodies of persons dying in the Monegar choultry relief camp, where the mortality was very high and almost entirely due to diarrhœa and dysentery. Numerous specimens of the various tissues and organs of such cases have been preserved, and will form the subject of minute microscopic investigation. As this, however, will necessarily be the work of some time, I shall in the meantime give a brief account of such of the results arrived at in the examinations conducted in Madras as appear to be of most practical importance.

"4. The general results of such examinations were confirmatory of the belief that morbid conditions exist which may with propriety be termed 'famine diarrhœa' or 'famine dysentery,' as the case may be. There are, without doubt, cases in which the symptoms of disease observed during life can be referred to no other origin save morbid changes and degenerations dependent on mal-nutrition. Many other cases occurring among the inmates of the relief camps, are, however, complicated by the supervention of other diseases, such as acute dysentery, pneumonia, &c., and although in the majority of such cases the conditions leading to true 'famine diarrhœa' may be distinctly detected, and in some the complications may be directly ascribed to their agency, yet the fatal termination is caused, or, at all events, accelerated, by the complications.

"5. The pathological changes essentially characteristic of 'famine diarrhœa and dysentery' consists in a softening and subsequent atrophy of the mucous membrane of the intestinal canal, due apparently to a process of fatty degeneration of the tissues, and leading to the destruction of the apparatus provided for the absorption of nutritive material. That such a process is sufficient to account for the phenomena of the disease observed during life, is manifest. The disintegration of the intestinal mucous membrane fully accounts for the disordered state of the alimentary functions. The pathological appearances also account for the failure of curative measures, improved diet, medicines, &c., in the treatment of the disease. Where once the complex structures of the intestinal mucous membrane have been so seriously affected by degenerative changes dependent on insufficient nourishment, they cannot be renewed, and no diet, however careful and generous it be, can be of any avail when once the means, by which alone it can be appropriated to the necessities of the body, have been destroyed.

"6. In conclusion, I must acknowledge the great obligation which I am under to the medical officers in Madras who assisted me in obtaining opportunities for investigation, and facilitated my work in other ways—more especially must I acknowledge the aid which was afforded to me by Mr. Cornish, the Sanitary Commissioner for Madras."

This disorder is ascribed by those who have studied its peculiarities on the spot to deficient or unwholesome food, exposure, and the presence of round worms in the intestines; and it was often brought on to an uncontrollable degree by a heavy meal taken when the body was in the last stage of emaciation from privation. One of the Friends' Commissioners was assured at Erris that (so far gone were they), "if the people got one strong dose, i.e., a full meal, it kills them immediately." ("Transactions of the Central Relief Committee," p. 202). Dean O'Brien is, as far as I know, the only writer who mentions cholera as prevailing in Ireland at this period. Alluding to the causes and consequences of the famine of '47-8, he says, in his tale of "Ailey Moore," which is, he assures us, a substantially true history of the events it portrays (pp. 260-1). "that fever and cholera spread as rapidly as destitution, for starvation and pest are travelling companions." Out of a strength of 1372 cases admitted to the camp hospital, 543 died in two months, and the average duration of the disease was three days and a half. If it occurs before the functions of digestion and assimilation are seriously impaired, the patient usually recovers; otherwise he does not, and thousands succumbed to it during the late famine in Madras. The patients rarely suffer, we are told, from cramps, but vomiting of fluid or mucus, tinged with blood, is not uncommon; and others suffer from such agonising pains in the stomach as cause them to roll about on the ground for relief. Others, again, pass very soon into a state of utter prostration, and death is preceded in many by muttering or groaning delirium. Dr. Cornish, the Sanitary Commissioner, has no doubt that there is, in most of these cases, ulceration of the intestine, just as all authorities agree to be the case in death from slow starvation; and the newspaper writer, to whom I am indebted for these facts, adds, after totting up the deaths that took place in one week, in two neighbouring camps, from this cause, that these figures (71 each in 4,000 and 5,000 residents) *represent a percentage per mille per annum of about* 850 *and* 750 *respectively.*

Whether these figures accurately represent the situation or not, I am just now unable to say. Neither have I ever seen any corroboration of Dr. Cornish's dictum about ulceration, as above; but an exhausting diarrhœa of this character has been noticed in every great crisis of this kind since history became a science, (*a*) and the agents of the Society of Friends everywhere found ("Transactions," &c. pp. 25, 56, 65, &c.) that "fever and dysentery [were] the invariable effects of famine" in Ireland in '47-8. Making every allowance for the natural or necessary misconception of these gentlemen, we have in their statement, nevertheless, ample corroboration of the facts disclosed within, and this looseness may be either the cause or the consequence of the degeneration described by Dr. Cunningham. It would also tend to show that prevention is the best, indeed the only, remedy for this state of things, for food and physic are clearly unavailing when this change is fully established, and hence the words *bis dat qui cito dat* should be the motto of every charitably disposed person or association, at this time, in respect of the crisis contemplated in this essay.

Touching the fever, of which so much has been said, and which was doubtless the main cause of the terrible fatality which followed the famine, it was, I think, clearly an after thought—a consequence, in short, of the insanitary conditions that were produced by protracted malnutrition and progressive bodily foulness and enfeeblement. Equally clear is it, I think, that this fever was the spotted typhus of the old military writers, the jail fever, &c., of Howard, and akin to, if not identical with, that which killed some of the sheriffs, judges, &c., &c., at Taunton, Oxford, the Old Bailey, and elsewhere, in his time, or earlier. Nor is this assumption discountenanced by the writers on this famine fever to whom I have had access, amongst whom I am, I regret to say, unable to include the Memoir of the late distinguished Dr. Stokes. Thus a medical man quoted by Mr. Trench is represented as saying that "the people die unconsciously to themselves; they are foolishly delirious; they die before your eyes. The pulse does not average fifty, there is water between it and your hand," and delirium, often wild and incoherent or feeble and flickering, is, we all know, often an accessory before the fact in death from typhus. The condition of the blood and pulse noticed by this gentleman is, of course, explicable on other and more obvious grounds, and Mr. Maguire calls the disease malignant typhus over and over again in his well-known work, "The Irish in America," pp. 80-1, &c. (*a*) Describing the quarantine at Grose Island, on the St. Lawrence, he says, that "of the enormous number of vessels that were driven by an easterly wind into that river (before the first week in June, 1847), there was not one free from the taint of malignant typhus, the offspring of famine and of the foul ship-hold;" and Mr. Sullivan is equally emphatic in the same direction in his article "The Black Forty-seven" in "New Ireland," vol. i., p. 137, whereat, he expressly says, that "it was the fever which supervened on the famine that wrought the greatest slaughter and spread the greatest terror." But it would be impossible, even if it were not needless, to pursue this subject any longer. These books are, or ought to be, within the reach of every Irishman, and the general fact is, moreover, not gainsaid.

The children suffered, I believe, more in proportion

---

(*a*) See *inter multos alios* Grote's "History of Greece," vol. vi., pp. 209 and 393; Froude's "History of England," vol. vii., p. 571; Alison's "History of Europe from the French Revolution," &c., vol. ii., p. 218; and Macaulay's "History," People's Edition, vol. ii., pp. 89-92; and a special correspondent of one of the papers wrote lately of the Turks, that "the poor creatures are decimated by dysentery, fevers—the typhus particularly—and by diarrhœa, and die in swarms." The thirtieth volume of the "Transactions of the Pathological Society of London," which contains an able and exhaustive, but withal, as I venture to think, somewhat inconclusive report on pyæmia, septicæmia, &c., has arrived since this was written, and finding in that report (p. 13) that "the symptoms produced by a fatal dose of the septic poison are . . . . gradually increasing muscular weakness, until the animal falls down, unable to stand; there are vomiting and profuse diarrhœa, the fæces at first being loose and whitish-grey in colour, and afterwards blood-stained or containing blood-clots . . . . the respiration and the heart's action become more and more feeble, until death ensues, sometimes preceded by cramps"—I am induced to ask if any conditions akin to these have ever been noted in connection with starvation?

(*a*) This book contains one of the most painful epitaphs that was ever written, and as it further tells a tale of woe and desolation such as have been rarely if ever exceeded in the world's history, I reproduce it here, and allow it to speak for itself. It runs as follows, and very similar testimony may be found in his interesting "Father Mathew: a Biography," pp. 391-2 and 418:—

To
Preserve from Desecration
The Remains of Six Thousand Immigrants
Who died of Ship Fever,
A.D. 1847-8.
This Stone is Erected by the
Workmen of Messrs. Peto, Brassey, and Betts,
Employed in the
Construction of the Victoria Bridge,
A.D. 1859.

during this dreadful period than their parents. The loss amongst them in the workhouses and elsewhere was simply appalling, and this loss was in great part, if not entirely, due to diarrhœa, or other cognate bowel disorder. But I have never before heard of the hirsute growth mentioned by Canon Bourke, neither can I now offer any sufficient explanation of its development; and he intimates, in the letter with which he has so obligingly favoured me, that he speaks of "it, not with metaphysical accuracy, but with moral certainty and truth."

After dwelling in sympathetc terms on the mere "holes in a bog, covered with a layer of turf, not distinguishable as human habitations from the surrounding moor," in which some peasants resided near Belmullet, co. Mayo, Mr. Forster (one of the Friends' Committee) observed that "the children exhibit the effects of famine in a remarkable degree, their faces looking wan and haggard with hunger, and seeming like old men and women. Their sprightliness is," he continues, "entirely gone, and they may be seen sitting in groups by the cabin doors, making no attempt at play or to run after the carriages." And he adds, further on, that "many of them are too weak to stand, their little limbs attenuated, *except where the frightful swellings had taken the place of previous emaciation.*" (The italics are mine, and the purport of them will be seen anon.) Another gentleman noticed that their (the children's) "legs swing and rock like the legs of a doll," and no wonder, seeing that they had probably been living for weeks previously on the little fat they had derived from their starving mother's breast, or on that with which dame Nature had originally endowed themselves. However that may be, it would be interesting to know if those who happened to survive were permanently enfeebled by the straits to which they were reduced at this epoch or not, and if marasmus or other wasting diseases were more prevalent during the crisis of the famine of 1847, &c., than before or since that event. I have seen it somewhere stated, that the female survivors of a certain famine were more fertile after than they were before that catastrophe, and racial traits of more enduring character have been elsewhere affected by misfortunes of this national magnitude. Whether any such or similar deteriorations took place, as a consequence of their unparalleled privations, among the denizens of the Green Isle, I am unable to say, but I rather incline to the belief that such was the case, and this is another reason why I address this communication to your journal.

And now to bring this already too lengthy paper to a close. What are we to think of the swellings referred to in the last paragraph, "in which," to use the words of an eye-witness, "first the limbs and then the body swell most frightfully, and then burst"? What, but that they are due to causes which produce dropsy in other subjects under the agency of deprivation or disease, and explicable on similar principles. But of this your readers are as competent to judge as I am, and the condition has many features in common with the Beri-beri of the East. I was not of an age at this time to know anything of such matters, neither have I seen anything like them since, and the only parallel I can find to it occurs in Lord Mahon's "Life of Belisarius," pp. 353-4. Commenting on the assertion of Procopius, that all those who were besieged in Rome by the Goths were, at last, constrained to exist entirely on wild herbs, and after further quoting him to the effect that this spare diet had imparted a wan and ghost-like aspect to the survivors, he says, "Now it may be observed that this wretched resource of hunger is attended with directly opposite results, rendering the body bloated, with many of the symptoms of dropsy," and it is, to say the least of it, singular that this very redundance of vegetable element should, when unaccompanied by other more substantial nutriment, produce a disease on land which is somewhat akin to that produced by the very opposite condition at sea.

He then quotes De Thou's account of the siege of Paris by Henry IV. in 1590, to the effect that "les pauvres ne bivoient que de feuilles, de racines et d'herbes, qu'ils allaient arracher d'entre les pierres. . . . On voyait ces malheureux enflés et hydropiques" (Histoire, vol. xi., p. 176). "I find," he continues, "in Gregory of Tours, the same result from a famine about one thousand years before, when the sufferers were obliged to feed on herbs. 'The people,' he (Gregory) says, 'tumefacti deficiebant'" (Hist. France, lib. vii., ch. 45), and famines are not, unfortunately, the only phenomena through which history repeats itself in Ireland.

◆

# THE PERIPHERAL NERVES IN CHRONIC LEAD POISONING. (a)

By ALEX. HARBINSON, M.D.,

**Assistant Medical Officer County Lunatic Asylum, Lancaster.**

*The State of the Peripheral Nerves in Chronic Lead Poisoning in Guinea-pigs.*—Dr. Gombault gives in the *Progrès Médical* for March 6, the results of experiments on this subject made in Professor Charcot's laboratory at the Faculty of Medicine. The facts, which will be published later, lead to the following conclusions :—

Saturnine neuritis in the guinea-pig is parenchymatous in character. Each nerve tube is affected separately, and independently of those adjacent. Two kinds of alterations are found associated in the same nerve. In one, the alterations resemble those observed in the lower end of cut nerves, and include the double phenomenon of Wallerian degeneration and consecutive regeneration; in the other, and these are oftenest seen, they are more like those described by Ranvier in the upper end of the same nerves.

As regards the Wallerian degeneration, the important fact is, that it does not necessarily extend throughout the whole length of the affected fibre, for in the continuity of a nerve, a healthy fibre is often seen which farther on shows a degenerated portion. Regeneration such as follows section of nerves, also occurs here. A large dark-bordered fibre may be seen to end abruptly and give origin to two slender fibres contained in the same sheath of Schwann.

The modifications of the second kind affect the nerve tube in a still more limited portion of its extent, whilst above and below the modified point the fibre possesses all its normal characters. Besides, everything leads to the belief that in the continuity of a fibre the same circumscribed lesion may be developed at several points at the same time with healthy intervals between. Two altered segments between three healthy pieces may be actually observed. As in the first kind of alterations, two orders of facts may be distinguished here: in one, the fibre is in process of degeneration; in the other, it is restored or on the way to restoration.

The degeneration is characterised by a granular state of the myeline or its disappearance more or less complete, swelling of the protoplasm, and multiplication of the nuclei in the interior of the sheath of Schwann. But here, and this is the important fact, the axis-cylinder modified or not in appearance, still remains.

Restoration shows itself by the presence of a series of slender, short, interannular segments provided with a sheath of myeline, very thin, but very regular, the sheath depressed sometimes by a single nucleus, sometimes by several separate nuclei. In the centre of the myeline sheath is an axis-cylinder relatively large. In either case, whether it be degeneration or restoration, the modified part is continuous at its two extremities with a portion of healthy fibre.

It follows from the facts stated here, that under the influence of slow irritation peripheral nerves undergo modifications different to those which a simple secti determines. This form of *multilocular circumscribed*

---

(a) *Le Progrès Médical.*

*renchymatous neuritis* differing from the forms of neuritis of internal origin hitherto recognised has therefore appeared deserving of special description.

◆

# PURE DRUGS: THEIR COMMERCIAL SOURCES AND PREPARATION. (a)

By ALEXANDER WILLIAM WALLACE, M.D.,
Medical Officer of the Riverstown Dispensary, Parsonstown.

It has for some time past appeared to me that something might be done by united action among the officers of Poor-law in Ireland, to lessen the evils of the contract system, by which medicines are supplied to the different unions. I have, therefore, directed some attention to the subject of the commercial source of pure drugs, and the means by which they may be obtained. I believe a considerable amount of the information I have obtained is not generally possessed by the medical profession. I have spent some time in making personal observations and inquiries on the subject, and what I have to communicate has either come under my own observation, or has been obtained from a trustworthy quarter.

Drugs which are of foreign growth are imported to London, where they are sold at auctions, which are held every fortnight. They are sold by samples, and are purchased by the wholesale druggists or the brokers. Every quality of drug is sold this way, the best and the worst, with every quality between, and purchasers are found for all, bad as well as good. The high-class druggists bring the purchases, which they have made, to their warehouses, examine and sort them. Those which are to be reduced to powder are sent to the drug mill. It is well known that a great amount of adulteration takes place in the process of grinding, but there are houses which are above suspicion in the manner in which they execute their work. Wholesale houses, as a rule, do not grind for themselves, as it is found to be done better and more economically by those who have made it a speciality. As an instance of the importance of conscientious preparation of drugs, I noted the treatment of colocynth. As is known, or at least ought to be known, to every medical man, it is the dried pulp, and not the rind or seeds, which contains the active principle. The fruit is imported in large cases containing a cwt. each. All conscientious manufacturers pick out the seed. But it is easy to see the opportunity this affords to a manufacturer of loose principle to increase his gains by leaving in a portion of the seed. He has certainly added nothing to what he bought, and the object may be effected by a little convenient carelessness on the part of the sorters. In the manufactory of Messrs. Richardson, where I saw the process of picking going on, the previous case of colocynth fruit to the one I saw, had yielded 28 lbs. of pulp from a hundredweight of fruit. This agrees pretty nearly with the estimate of Prof. Tichborne, who states in a paper in the *Pharmaceutical Journal* of September 21st, 1878, that he found colocynth fruit to contain about 20 per cent. of pulp. Chemical products, such as the alkaloids and minerals, are made by the chemical manufacturers. It is rather a curious fact that almost all the morphia used in the United Kingdom is made by two manufacturers in Edinburgh. Several substances are manufactured of great purity in Berlin. These are especially chloral, salicine, and its compound, iodoform and monobromated camphor. Wholesale druggists usually confine themselves to the manufacture of tinctures, concentrated infusions, ointments, extracts, pill masses, and pills.

It is manifest from this enumeration of the different sources of the materials which form the Pharmacopœia, that a very special combination of scientific, technical, and business qualifications is needed for carrying on this business effectively. It ought not to be a mere appendage to the business of wholesale houses which are chiefly engaged in supplying grocers with rice, oils, mustard, dried fruits, &c., or are occupied with the manufacture of paints—houses of which neither the principals nor *employées* have any pretentions to scientific or technical training. Drug manufacture ought to occupy the undivided attention of those engaged in it, and they ought to possess a thorough acquaintance with the physical and chemical qualities of the crude drugs; that tact which is only acquired by long practice, combined with technical skill, which can estimate the true value of a drug business; the capacity which has established relations with the best houses for the supply of manufactured articles; and, finally, there must be a trained staff of operators for the manufacture of those preparations which are made on the premises. It is manifest that these conditions can best be realised by houses of long standing, who have grown into the trade as it has gradually developed into its modern properties.

I have reason to believe that a fertile source of inferiority in the quality of drugs is due to carelessness in their storage. I have seen a drug store containing such perishable substances as digitalis and hyoscyamus exposed by open doors and windows to the entrance of the moisture-laden winds of winter, there being no means whatever of warming it. The consequence was that very little of the characteristic odour remained in the hyoscyamus, and no doubt the other drugs were equally, though less obviously, affected. There is good reason, however, for believing that the deterioration of drugs is often of a more positive character. Be that as it may, the fact is patent that the contractors for the supply of drugs to Irish unions tender, at prices which would be ruinous if the preparations cost the current market price for good articles.

Through the courtesy of Messrs. Richardson and Co., of Leicester, I was permitted to inspect the whole of their manufactory. Though not professing to be an expert in the examination of drugs, I was, of course, able to recognise in a general way the excellence of the quality of their crude drugs, and could appreciate the arrangements for the storage of the drugs in warm dry rooms. The entire attention of the firm is devoted to drugs, and cleanliness and order prevail everywhere.

Passing by the better known processes of preparing decoctions and infusions in copper evaporating dishes, heated by high-pressure steam, I felt most interested in the pill department. When it is considered that the published formulæ of the firm for pearl-coated pills amount to about 650, all of which are kept in stock, and that over 6,000 private formulæ are in the books, and are prepared whenever required, it will be seen what an amount of organisation is requisite in order to secure order and regularity. The most curious part of the process is the manufacture of pills from the mass. The mass is put in a cylinder, having a perforated plate in the bottom, and pressure is made above. The material is thus forced through the hole in long rolls like worms. As pill masses vary in specific gravity, the number of plates required to produce rolls of such diameter that they can be divided into pills of the proper weight is very large. The rolls are then dropped into a hopper, whence they find their way between grooved rollers, which are driven at considerable speed by a treadle. By these they are at once divided into pills of the required weight. The pills are then spread on a table, imperfect ones are picked out, and the others rolled and worked under a board till they are perfectly round. They are then dusted with a powder (not lycopodium), which dries the surface and prevents them from sticking together. At this stage of preparation considerable quantities of them are sold as "uncoated" pills. If they are to be "coated," four successive layers of the impervious material are applied, and they are finally polished. They are then put up in canisters or bottles, and kept for sale.

It is obvious from the details I have given that the opportunities for the adulteration of drugs are manifold. I believe the only effective remedy for the evils of the present drug supply to dispensaries would be the appointment of a qualified inspector of pharmacy, whose sanction should be required to every tender before it was accepted by the guardians, and who should have assistants to inspect every dispensary, and see to both the quality of the drugs, and the condition in which they were kept, for there is good reason to believe that some medical officers are perfunctory in the discharge of their pharmaceutical duties. While fully recognising this as the proper remedy for existing evils, I am persuaded that those medical officers who wish to be rid of the present condition of things, until a better one is inaugurated, have the remedy in their own hands, by ordering the preparations of firms of recognised standing. I have reason for thinking that if this experiment can be judiciously made, if medical officers are satisfied to give small orders at first, and to be very careful that there is no waste, and that no unnecessary expense is incurred, the L.G.B. will offer no opposition, if they do not look upon the arrangement with actual favour, and Boards of Guardians will find that there is little, if any, additional expense incurred. All, however, will depend on the zeal and discretion of the medical officers.

---

(a) Read before the Irish Pharmaceutical Society, *Mar.* 2, 1880

While I have thus drawn special attention to the firm of Messrs. Richardson and Co., I do not for a moment mean to imply that there are not other firms quite as much above all question, but I felt that before advising the adoption of such a course as I have proposed, it was proper that I should make personal inquiries as to the sources of the supply of medicines; and having for a considerable time used Messrs. Richardson's preparations, I requested their permission to see their establishment, and make myself acquainted with its details, with the very satisfactory result I have mentioned.

## SUBCUTANEOUS EMPHYSEMA DURING PARTURITION.

By W. LEATHAM, A.B., T.C.D., &c.,
Medical Officer Coalisland Dispensary.

Having read in the *Medical Press and Circular* of Feb. 25th, a report of a case of subcutaneous emphysema, occuring during parturition, by Dr. Peper (*Le Praticien*, Feb. 9), and as such cases are very rare, and might be a source of considerable alarm to young practitioners, the disease coming on so very suddenly, and without the least expectation of any untoward circumstances about to occur, I think it well to mention a case of this kind that I met with in my practice some years since. One evening, about 9 p.m., I was sent for, to attend a woman in her confinement (primipara), and found her in the first stage of labour. The os uteri was dilated to about the size of a half-crown; the pains returning at intervals of about twenty or thirty minutes, and had been going on, I was informed, for about two hours before I saw her; although it was evident to me that the case would be a tedious one, I remained in attendance on her during the night. As labour progressed, the pains became very severe, and as she would not permit the use of forceps there was nothing for me to do except to wait patiently.

On the following morning, about 6 a.m., when the head of the child had for some time been pressing on the perineum, and the pains returning at very short intervals, and so violent that it was painful to listen to her, I was surprised to see the right side of her throat, her face, shoulder, and down her arm, suddenly become swollen to an alarming extent. In the swelling, crepitation was very distinct. She, at the same time, became cold and very pale, and her pulse was scarcely perceptible. Fortunately the pain that brought on these symptoms also expelled the head of her child, so that her labour was soon afterwards over, and in about ten days the emphysema had completely disappeared. Since then I have attended her in two other confinements, and she has not had the slightest return of these symptoms. This must be my excuse for reporting this case after such a lengthened period, as I have not read in any other a subsequent history of whether there was any return of the emphysema or not. In my case there certainly was not, although in each subsequent labour the pains were unusually strong, and I expected that in a patient having previously suffered from this disease there would have been a tendency to its recurring, as it is only reasonable to suppose that whatever rupture took place in the pulmonary vessels would leave the parts so weakened as to make it likely to occur again.

The explanation of this accident is, over-distension and rupture of the air cells, and the escape of air into the interlobular tissue of the lungs, and thence through the mediastinum into the common cellular tissue, appearing, first about the lower part of the throat, face, and shoulder, and extending down the arm and side. The treatment is to diminish the violence of the respiratory effort by which the air is forced at each respiration into the mediastinum. Emphysema from this cause may also occur in whooping-cough, as mentioned by Drs. Johnson and Beattie.

# Clinical Records.

## ERYSHEMA AFTER TAKING CALOMEL.

Dr. Engelmann (*Berlin Klin. Wochen.*) has observed a case of generalised erythema following the exhibition of several doses of calomel.

M. W., æt. 42, who had previously had good health, had, after a voyage, a diarrhœa treated at first by opium. When the author saw him he complained of want of appetite, tenesmus, and diarrhœa: tongue foul, temperature and pulse normal. Calomel, three doses of 15 centigrammes, were taken in the course of the afternoon. Two hours after the last there was general malaise, heat of skin, photophobia, dryness of mouth and nose, raucous voice. The face swelled and became the seat of redness, which soon extended over the whole body. Smart fever, thirst, insomnia. The next day the general appearance was similar to that of intense erysipelas The face swollen, especially the eyelids; eyes opened with difficulty, skin tense and of a scarlatinal redness as far as the hair. Conjunctivæ injected, integuments of the nostrils dry; buccal and pharyngeal mucous membrane slightly red. A thick coating over the whole tongue, except at the point, which is slightly red. The redness of the body is more marked on the uncovered parts; it disappears on pressure, soon to reappear. No infiltration, except on the face. Temp. 40° C., pulse 120. Urine scanty, dark, without trace of albumen. Voice raucous, want of appetite, thirst. The patient complains of heat and itching on the hands, the soles of the feet, the ears and the scalp, mouth dry, heat of the conjunctivæ.

There did not appear to be any question as to erysipelas or scarlatina, but what affection of the skin had one to deal with? The author considered it a mercurial eruption because the patient had twice before had similar ones; once after taking for a long time mercurial pills; the second time after being for a long time in the company of a person who amused himself by burning "Pharaoh's serpents." The characters of the eruption were exactly similar.

The progress presented no peculiarities; the fever and eruption disappeared in a few days, but slight œdema of the face remained for some time. Cure was complete in fourteen days.

# Special.

## THE DIGESTIVE FERMENTS AND ARTIFICIAL DIGESTION.—II.

It is quite clear then, from what we saw in a preceding portion of this article, that the pancreatic fluid is indeed a most important factor in the digestion of our food. It contains ferments which both convert starch into sugar and proteids into peptones, while further it emulsionises fats so that they can be taken up by the villi of the intestines. It is obvious then that the whole of our digestion might be done artificially by a preparation of the pancreatic fluid under certain circumstances. What, then, are these circumstances, and what the difficulties to be encountered? The use of pancreatic preparations has obtained for some years now, with but partial success however. The difficulty lies in the fact that these pancreaticferments are destroyed by the presence of an acid, and there is the acid stomach to be encountered. This has hitherto been the obstacle to be overcome in the way of aiding digestion artificially by the use of pancreatic fluids obtained from animals. The plan which has usually been adopted has been to wait till the termination of gastric digestion, and then give the pancreatic fluid under the guardianship of an alkali. The effect of the alkali is to neutralise and do away with that acidity in the stomach which is fatal to the activity of the pancreatic ferments. By such means assimilation and digestion have been much improved with many dyspeptics, especially as regards the assimilation of fats. But the effects of the pancreatic diastase upon starch must not be overlooked. The action of the salivary diastase upon starch is very brief, for it ceases as soon as the contents of the stomach become acid; consequently we must conclude that very much of our starch digestion is carried on beyond the pyloric ring.

The action of the pancreas is most important in the assimilation of hydro-carbons, and the defective functional activity of the pancreas must be regarded as one of the gravest factors in the production of that mal-assimilation which looms in the distance as one of the greatest evils we will have to encounter. The stimulation of the pancreas by ether, first propounded by Dr. Balthazar Foster, has been investigated by an American committee, and Dr. Foster's views have met with their distinct corroboration and approval. We have then two measures at our command when pancreatic secretion is insufficient; we can stimulate the organ to more energetic action, or we can furnish the requisite ferments artificially.

As regards the requirements of dyspeptics, experiments illustrate what clinical experience has long taught as to the condition of matters at or towards the end of the digestive act in the stomach. It is found that, "if you subject any native article of food—say milk, bread, or meat—to artificial digestion with pepsin and an acid you utterly destroy the grateful odour and taste and the inviting appearance which made it desirable as a food, and you convert it into a nauseous mass from which the human palate turns away in disgust. The unsavouriness of digested food is, however, not due to any ill-taste or smell inherent in the peptones themselves, which, when purified, are both odourless and tasteless, but to a number of bye-products of various kinds, volatile acids, and other matters, which accumulate as digestion proceeds. One of these bye-products is a bitter flavour, which is a constant and noteworthy characteristic of gastric digestion." This behaviour of artificially-digested food is strikingly in accord with the complaints of many dyspeptics in whom these bye-products are largely present. Reading the clinical phenomena by the light of artificial digestion by pepsin and an acid, it appears that in many cases of dyspepsia the trouble lies as much or more in the formation of these undesired bye-products than in the imperfect formation of peptones. The patient is imperfectly fed, while his digestion is rendered disagreeable by the formation of acid and bitter bye-products. Further experience of the use of artificial pancreatic preparations will instruct us as to how far, when the digestive act is encumbered by the accumulation of these bye-products under pepsin and an acid, it is well to arrest gastric digestion by an alkali, and institute pancreatic digestion in an alkaline medium. There seems much ground for hope that by such means imperfect natural digestion may be greatly aided. Of course, it would be very easy to procure peptones freed from these objectionable bye-products, but their price forbids their general use. To aid gastric digestion by pepsin and an acid is all very well as regards the albuminoid elements of our food; but when accomplished it leaves the digestion of hydro-carbons unaffected — a most important matter in tissue-nutrition. The gradual loss of power to assimilate fats is, and has been for some time, recognised as one of the most serious factors in the production of phthisis. For many phthisical patients there are where emaciation proceeds to a ghastly length, while the lung mischief is small and quiescent till the few last days of life, when it spreads rapidly. The whole value of cod-liver oil lies in its being the most easily-digestible of all fats, and thus often capable of being assimilated by digestive powers unequal to the digestion of other fats. By recognising more distinctly the important part played by the pancreas in the digestion of hydro-carbons we will in the future contend more successfully with those early stages of phthisis where the lung mischief has not reached that stage when cure is unattainable.

The impetus given to our therapeutic measures by Dr. Roberts' investigations is tremendous, for they supply most important information on a subject of cardinal importance, which, until recently was shrouded in mystery. The right and proper use of stimulants to the pancreas, and of artificial pancreatic preparations, now stands out boldly, and it is in the power of any practitioner who chooses to take the trouble to think upon the subject to use them aright, for all difficulties have now been removed in the way of comprehension of the matter. As to pepsin fluids, many men have lost faith in their efficacy because many of the preparations were rendered more or less completely inert by the method of preparing them; but even when an energetic *liquor pepsinæ* is procured it can only aid in the digestion of albuminoids. For this purpose the trypsin of the pancreatic fluid is equally potent with pepsin, while the other constituents of the pancreatic fluid possess a potent influence on the conversion of starch into sugar, and in the emulsionising of fat, by which means it can be taken up by the lacteals, and to a small extent by the intestinal veins. Consequently our therapeutic measures, so far as dietary is concerned, must take the direction of aiding pancreatic digestion, for it is in the digestion of hydro-carbons that the improvement will turn when there is emaciation or wasting. The improvement brought about in pulmonary phthisis by the exhibition of cod-liver oil is due to the tissues being so provided with the hydro-carbon elements, whose absence leads to disease and death. If the patient can be enabled to assimilate a sufficiency of fat the downward progress is arrested, and often improvement instituted. The recognition of this fact, and the introduction of cod-liver oil by the late Professor Hughes Bennett, have always been regarded as solid additions to our knowledge of the nature and treatment of phthisis pulmonalis. If, further, we can not only furnish to the body a very easily digestible fat, but can provide means of procuring the digestion and assimilation of fat in the body, a most important step forward in the treatment of wasting disease is accomplished. Old practitioners are always anxious to secure the integrity of the digestive processes in their treatment of phthisis; hence the value put by many in the old-fashioned bismuth and alkaline mixtures, and the regulation of the primæ viæ, now too much neglected. Our first duty in the treatment of wasting disease is to check all excessive out-goings, as night sweats, diarrhœa, leucorrhœa, &c., and then to place the digestive organs in a good condition so as to secure the assimilation of a sufficiency of food for proper and healthy tissue formation; after then, and only after then, can tonics be given with advantage. Not only can we aid the natural attempts at digestion, but we can artificially digest food out of the body so as to tax the natural efforts to a minimum extent only.

This will form the subject of a subsequent and concluding article.

## FRANCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 12.

At the Académie de Medécine M. le Roy de Méricourt related a case on behalf of two practitioners. To an infant three weeks old was given by mistake a teaspoonful of laudanum instead of syrup of chicory. The narcotic was administered at 9 o'clock in the morning. A medical man who was called in ordered an emetic, more to content the parents than anything else; afterwards he himself gave a decoction of gall nuts and strong coffee and waited the result. Two hours after the ingestion of the laudanum the child was attacked with convulsions followed by coma, in which state it remained till seven in the evening. After each convulsive seizure the heart seemed to stop. There was no vomiting nor diarrhœa. Another medical man was sent for, and artificial respiration was decided upon, which was resorted to unremittingly after each convulsive attack. Towards night the somnolency diminished and the child opened its eyes. The following day reaction commenced, the pulse marking 180 in the minute, milk and wine were administered, and on the third day the child took the breast.

The principal communication made at the last meeting of the Surgical Society was that of M. Duplay, of the Lariboisière Hospital, upon the treatment of epispadias. Six years ago M. Duplay detailed his operation for hypospadias, and since that time he has succeeded five times. One patient in particular married after the operation, and is the father of several children. This week M. Duplay brought forward two young patients on whom he operated with complete success. The method of M. Duplay closely resembles that of Tiersch, of Leipsic, which consists in firstly straightening the penis, which is generally curved in epispadias; secondly, the reunion of the walls of the canal near the opening; and thirdly, in grafting upon the opening itself skin borrowed from the prepuce, which is in these cases so exaggerated. To fulfil the first indication M. Duplay made an incision on the dorsal surface of the penis, and maintained it in a pendent position until cicatrisation took place. Afterwards he pared the opposing surfaces of the corpus cavernosum, and brought them together by means of the suture. A catheter was previously placed in the fissure. M. Duplay completed the operation by covering the dorsum of the penis by a piece of skin taken from the prepuce.

At the same meeting a member read a report of lithotomy performed on a child twelve years old, who presented all the symptoms of a stone. The lateral operation was chosen, but by reason of the volume of the calculus it was found necessary after proceeding a little way to change it to the bilateral. In spite of this the stone was unable to be seized by the instrument. On introducing the finger the stone was found to be encysted. After this operation the patient had a perineal fistula. A few months afterwards M. Simonin (the operator) performed again, but this time through the rectum, but the calculus was so adherent to the mucous membrane that it was with considerable difficulty it was extracted; it was the size of a hen's egg. The rectal wound admitted the three fingers together. The patient left the hospital six weeks after the operation, but returned in a month with a recto-vesical fistula.

The *Gazette des Hopitaux* records the case of a uretero-uterine fistula cured by extirpation of the kidneys. The operation was performed by Zweifel (Erlangen). A woman aged twenty-nine had five very difficult confinements; in the last forceps had to be applied, and a fistula uretero-uterine resulted. Zweifel discovered that the left ureter was alone implicated. Several times he tried to dilate the neck of the uterus in order to see the rent in the ureter, but failed; he afterwards tried to obliterate the canal of the cervix, but reunion would not take place. The woman desired repose from these unfruitful attempts for a little time. She became again *enceinte*, and abortion was effected with considerable difficulty. The fistula persisting, Zweifel sought to create a vesico-uterine fistula combined with occlusion of the cervix. Failing in this on account of a phlegmon provoked by forced dilatation, there remained but one other means, that of making a vesico-vaginal fistula with oblique occlusion of the vagina. This last perspective was firmly rejected by the woman and her husband. There was nothing left for the indefatigable Zweifel but to extirpate the kidney. The operation was performed, and the patient four months afterwards was perfectly cured.

MR. JONATHAN HUTCHINSON, F.R.C.S., was, last week elected Consulting Surgeon, and Drs. H. S. Gabbett and W. H. White, Assistant Physicians to the Royal Hospital for Diseases of the Chest, City Road.

# Transactions of Societies.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 19.

E. HEADLAM GREENHOW, M.D., F.R.S., in the chair.

Mr. THOMAS SMITH on a case of

### SPONTANEOUS GANGRENE OF THE THUMB AND FINGERS OF THE RIGHT HAND.

This occurred in the case of a child, æt. 3, who was admitted for an abscess in the thigh, which ran a favourable course under antiseptic treatment. The child was slightly ricketty, well nourished, spleen palpable, extremities inclined to be cold and blue. Ten days after admission, while in bed, in the early part of October, the right hand and fingers became cold, blue, and quickly gangrenous, a line of demarcation forming at the metacarpal joints. There were no signs of plugging of any of the large vessels of the limb. While the gangrene was in progress the child suffered from pyrexia, but in ten days time regained her ordinary state of health. The fingers and thumb separated at the metacarpal joints. Mr. Smith could not account for the occurrence of gangrene; no signs of renal disease, cardiac mischief, or arterial embolism were detected. The child, though liable to cold hands and feet, was warmly clad, well fed, in fair health, and yet, as if by some accident, one hand had become chilled beyond the limit whence recovery was possible.

Mr. HOWARD MARSH inquired whether there were any threatened signs of gangrene in the feet, &c.

Dr. SYMES THOMPSON said that five or six years ago he was called to see a patient, a Russian general, in good health, but who was unable to walk for more than five or ten minutes consecutively. The feet grew very cold, and altogether the phenomena were inexplicable. Dr. Thompson consulted by letter with the patient's own physicians in St. Petersburg, but without deriving any material assistance to aid in treatment. He had since heard that both extremities had become gangrenous, the mortification extending from the toes to the ankles. There had been no signs of atheroma, or any change in the pulsation of the tibial or other arteries. The symptoms were purely negative in character.

The PRESIDENT suggested that the condition exhibited in Mr. Smith's case might be similar to that which induces ulceration of the parts affected by chilblains.

Mr. CROFT asked whether the blood had been examined to determine the relative proportions of red and white corpuscles. Such examination, he said, was rarely made; but it is advisable wherever the cause of gangrene is not obvious; and also to ascertain the nature and amount of the fibrin elements. Gangrene, he continued, may be consequent on a derangement of the nerve supply to a part; to impaired vascularity, such as degeneration of the arterial walls, as might have been the cause of mischief in the case related by Dr. Thompson. Plugging of the vessels may also occur from the formation of clots due to change in the blood itself, and in no way dependent on disease of the vessels. This alone affords an explanation of the "white leg" in subjects of amenorrhœa, the common or external iliac vein becoming plugged up, not in the distal portion, but at a point nearer the parts involved in the menstrual functions. In Mr. Smith's case the child was in ill-health, as evidenced by the abscess in its side, and in this state the blood may have been peculiarly favourable to formation of clots. Mr. Croft concluded by demanding whether any symptoms of septicæmia were observed by Mr. Smith during his treatment of the case.

Mr. GOULD asked if any symptoms of carbolic acid poisoning had been noted. From personal experience he thought the effects described might be due to this cause.

Mr. MACNAMARA explained that the white corpuscles of the blood are destroyed after poisoning by carbolic acid. When examined in the dog they are found to be motionless, and it is possible that the clots formed were due to this action of the antiseptic agent on the leucocytes.

Mr. SMITH said the child was admitted into hospital Oct. 4. On October 14 no signs of carboluria had appeared, nor did they set in until three weeks after the later date. He had noticed in the Children's Hospital that in susceptible cases the symptoms of phenol absorption were early apparent, but in the case under discussion the gangrene had continued for one month before anything of the kind was observed. He thought, with the President, that the disease originated with chilblains, and this opinion was strengthened by the freedom of all other parts of the patient's body from both chilblains and gangrene. There was no septicæmia. The blood was not examined. The spleen was distinctly palpable. On admission the child's hands were colder and bluer than usual, and it was of the nature described as "flabby."

Mr. Thomas Smith on

### TWO CASES OF CONGENITAL CYSTIC HYGROMA.

Both patients were between three and four years old, with large cystic hygromata, occupying the right axilla, right side of the neck, and extending on to the upper arm. These were admitted into the Children's Hospital within a week or two of one another. In the one case inflammation was excited by the introduction of three carbolised catgut setons, in the other it had resulted from a blow. After a lengthy convalescence, in the first case of six months, and in the last case of five months, the patients were discharged, and were now, more than a year afterwards, cured, the tumours having shrunk so as to be unnoticeable. Mr. Smith remarked that since his published experience of the disease in the Bartholomew's Hospital Reports, he had seen a large number of cases, and had been still more convinced of the uncertainty of the prognosis in the disease where left to itself, as it at one time would make progress, and at another recede; indeed in the same growth, at the same time, one cyst would be increasing while another was drying up. In respect of treatment of a curative kind, he had nothing better to recommend than that of attacking the cysts with carbolised catgut setons, and thus exciting inflammation in them. Though this plan was not devoid of risk, yet it was less dangerous than removal, and much more reliable than injection by iodine tincture. He had never tried Morton's iodo-glycerine solution, but thought it promised well.

Mr. W. Haward thought the introduction of a seton the simplest treatment to pursue in these cases. Even it, however, is dangerous, but nevertheless, where necessary, it ought to be adopted. He related a case where extravasation of blood into a cystic tumour took place after a fall. The child was in fairly good health, there was little constitutional disturbance, and the large hygroma disappeared, even the parts not affected by the extravasated blood being absorbed in greater part. In another case a large axillary cyst, extending over the arm, underwent spontaneous cure without injury. He could not say certainly the patient had not fallen, and so excited absorptive action, but only that no inflammatory symptoms were noticed. It was observed, however, that *pari passu* with the decrease in size of the upper cysts the lower-situated ones grew more tense. Probably, as in hydrocele, &c., the irritation to which the cyst is subjected suffices to excite reparative changes. In all cases he thought it advisable to watch the progress of the tumour awhile before interfering in any way, since, as in nævi, the trifling injuries received by the patient in tumbling about may oftentimes be productive of spontaneous recovery.

Mr. Godlee remarked that a case had come under his treatment within the week in which a small tumour presented. It had rapidly increased to three inches in diameter; he removed it, being under the impression that it was a fatty tumour, but on examining stained sections of the small cysts composing it, he recognised typical lymphatic endothelial cells. Recovery took place rapidly.

Mr. Parker related the history of a case of hygroma treated at the Children's Hospital, Great Ormond Street, in which the tumour dispersed after the passing into it of setons, but refilled subsequently. Scarlet fever, however, occurring later on the child, the growths entirely disappeared. Sections of a deeply-seated tumour removed from another patient by Mr. Maunder, showed nucleated sarcomatous tissue with wide spaces existing in it, and unlike the kind mentioned by Mr. Godlee. In a third case a large single-cysted tumour yielded to treatment by setons, and dwindled to a small piece of flabby skin in three or four weeks. He considered Mr. Smith's case exceptional.

Mr. Howard Marsh.—The older surgeons were much troubled by these growths, the correct treatment of which Mr. Smith was the first to explain. Removal was attended with non-success, Mr. Cæsar Hawkins having been amongst those who failed in this way. Mr. Holmes, in pursuing this practice, had once been compelled to cut so deeply that he exposed three inches of rectum in the operation. He himself (Mr. Marsh) had once removed a cystic tumour from the cheek of a child nine days old, the operation being rendered imperative by danger of suffocation through spreading of the growth to the pharynx. He had to make an incision over the corner of the jaw and above the zygoma; then scooping out the temporal fossa, half the zygoma was cut away. Recovery took place. The growths are not limited to particular regions, but may be found on the arms, legs, thorax, &c., as well as on the neck. He agreed that the tumours should be left alone if possible, since dangerous and fatal symptoms, due to inflammation and exhaustion, may follow even the introduction of setons.

Mr. Parker added that he was at the time treating a woman for a tumour of the kind under discussion. He had partly emptied the cyst, and injected iodine solution into it. The operation was followed by pain.

Mr. Smith said operative procedure was essential in those cases where spontaneous cure did not arise in time to prevent all danger of suffocation. The risk was undoubtedly great. The position of the tumour was not a confined one, several instances in point having been recorded. The substratum of the tumour is adenoid tissue; and the disease may be found in both axillary spaces. That it may recur has been shown by Mr. Cæsar Hawkins, who relates a case of return after an interval of twenty years.

Dr. de Havilland Hall read an abstract of

### A CASE OF INTRA-THORACIC SARCOMA.

H. A., a youth of 19, was admitted into Westminster Hospital, under Dr. Hall's care, on December 5th, 1879. The patient stated that up till nine weeks previous to admission he had enjoyed good health, that he caught cold while playing at cricket, and that his illness began with languor and loss of flesh. He applied to a medical man, who told him that he was suffering from pleurisy. On admission he complained of slight cough, but with no expectoration, and of shortness of breath on exertion. Decubitus on the left side. Over the right lung there was good resonance on percussion, with puerile breathing. The left chest was absolutely dull up to the second rib, the dulness transgressing the median line; above second rib the resonance was somewhat boxy; posteriorly there was dulness to spine of scapula, and a tympanitic note above. The side was immoveable, with marked rounding, and there was bulging of the interspaces—vocal fremitus not quite absent. Breath sounds inaudible, except faintly at apex and along spine; a faint creak audible at angle of scapula. Heart impulse one inch to inner side of, and one inch below, right nipple; sounds clear. A diagnosis of pleural effusion was formed. The patient was accordingly tapped in two or three places, but no fluid followed, the end of the instrument being blocked up with a little "cheesy," flaky matter. Two days after admission a free incision was made in the fifth interspace with antiseptic precaution; on introducing the finger a mass of soft "cheesy" material was found in every direction; a drainage tube was left in the opening. No marked alteration occurred till December 21st, when the patient appeared much worse, suffering from shortness of breath, and he coughed up a little frothy rusty sputa. The next day there were the physical signs of pneumonia of the right base, and he died on the 23rd. The post-mortem examination showed the whole of the left pleural cavity was occupied by a soft brain-like mass, which microscopical investigation showed to be a round-celled sarcoma. The left lung was collapsed and lying along the spine. The heart was pushed over to the right; the outer border of the right ventricle extended five inches to right of middle line, the tumour itself extending two inches to the right of the same line. The lower lobe of the right lung was noncrepitant, and resembled damson cheese in colour and consistence. Dr. Hall remarked on the extremely short history of illness given by the patient. He pointed out that the physical signs were in every particular those of an extremely large pleural effusion, with the exceptien that vocal fremitus was not quite absent. He drew attention to the rapid growth of the tumour, as shown by the increase in the area of dulness and the displacement of the heart which took place under observation. He regretted that he had omitted to examine microscopically the so-called "cheesy" matter which adhered to the aspirator after it was withdrawn; examination of this substance would doubtless have sufficed for an exact diagnosis before death. The growth apparently sprang from the anterior mediastinum.

Dr. Douglas Powell.—The aspirator affords the only efficient means of diagnosis in cases of this nature. The pressure signs of lymphomatous tumours are not easily recognisable; they often surround vessels, and only at the last exert pressure on them. Hence puncture alone can afford any reliable information of their structure.

The **President** thought it a matter for regret that Dr. Hall had omitted to examine the material brought away by the aspirator-needle. He did not think it so easy as Dr. Powell suggested to diagnose fluid. He recollected two cases of the kind in Middlesex Hospital, in which puncture revealed no fluid, and the assumption was favourable to the existence of solid growths, whereas this was not their true nature. He agreed that the case under discussion was one of lymphoma. This differs from malignant disease, in regard to the pressure exerted on the contiguous structures.

Mr. F. T. **Tayler** described a case of pneumonia which had been twice tapped for fluid without positive result. It was seen by Mr. Haward, who introduced a very long needle, with which he was able to reach a collection of fluid. He concluded, therefore, that one or two punctures were not always sufficient to establish the certainty of diagnosis.

Dr. **Powell** inquired whether Dr. Hall had noticed any hæmoptysis in his case.

Mr. **Gould** explained that when he had tapped the patient as explained, the tube of the aspirator became plugged, and this led to the belief that it was impossible to reach the wall of the cyst.

Dr. **de Havilland Hall** said the belief in the sarcomatous nature of the tumour was founded on Mr. Butlin's opinion of its histological structure. A specimen of it lay on the table under a microscope. The history of the case opposed the idea of the growth being malignant. The previous health of the patient had been good. The illness had been sudden; there was pleuritic effusion, growing rapidly, and displacing the heart very much in a few days. On account of these symptoms repeated puncture seemed to be called for. There was no hæmoptysis.

## HARVEIAN SOCIETY.

### March 18th, 1880.

The President, **Henry Power**, Esq., F.R.C.S., in the chair.

### MALIGNANT DISEASE OF THE HIP.

Mr. **Pepper** gave an account of a case of malignant disease of the hip, and exhibited a specimen. It occurred in a woman of 52, who had lost flesh, and who suffered great pain in her knee and hip on the right side. Pulsation was felt outwardly and per rectum. This pulsation was expansile. A bruit was heard locally. The tumour felt so much a fluid one that it was diagnosed as an aneurism, and the common iliac was tied, death being the result. Under the microscope a section of the tumour showed that it was an alveolar sarcoma, with great regularity in the distribution of the stroma and the cells.

Mr. **Frost**, Mr. **Bryant**, and Dr. **Fitzpatrick** spoke on the case, after which Mr. **Pepper** replied.

### THE VARIOUS METHODS OF DEALING WITH THE PEDICLE IN OVARIOTOMY.

Mr. **Knowsley Thornton** then read the paper of the evening on this subject. Having described the normal structures of the pedicle, he said it might also contain the round ligament, or the Fallopian tube. When it contained the tube it was well to remove it with the pedicle. In dealing with the pedicle there were three points to be attended to: (*a*) security against hæmorrhage; (*b*) not to irritate the nerves unduly; and (*c*) to see that the muscular fibres did not drag the stump out from the ligature. As to the different measures which had been adopted to attain these ends, he should follow Peaslee's plan of taking them chronologically. 1. Macdowell's plan of ligature, bringing the ends out at the lower angle of the wound; 2, long ligature, which was liable to leave a putrid mass in the abdomen; 3, transfixion of pedicle; 4, ligature of the vessels separately, along with the use of leather ligatures; 5, animal ligatures; 6, bringing the ends of the ligature out by the vagina; 7, torsion; 8, the écraseur; 9, the clamp, which is liable to leave a ventral hernia, and if the Fallopian tube is included there is apt to be bleeding at the menstrual periods—he approved of the clamp in uterine tumours; 10, acupressure; 11, figure-of-eight ligaturing; 12, actual cautery; 13, to cut peritoneal flaps; 14, forceps for torsion; 15, enucleation of the cyst; 16, Peaslee's knife and drainage tube. There were other slight modifications. Mr. Thornton then described his own practice, preferring the ligature and adopting Listerism, but adapting the treatment to the exigencies of each case.

The **President**, Dr. **Heywood Smith**, and Mr. **Bryant** spoke, after which Mr. **Thornton** replied, and the meeting then adjourned.

## THE LUNACY LAW AMENDMENT ACT.—III.

The most obnoxious feature in the whole of Mr. Dillwyn's highly distasteful Bill is perhaps contained in the 13th section, which makes it lawful for everybody to meddle with every other body's lunacy affairs, and opens the door to inconceivable confusion and turmoil in the future. By this precious section any person may obtain from the Commissioners in Lunacy an order for the visitation and examination of any person confined as a lunatic in an asylum, by two registered medical persons, and the Commissioners are bound to order the release of any lunatic who shall be certified by two medical persons, after two separate examinations, at intervals of not less than seven days, to be in their opinion harmless. Thus a few busybodies and lunatics' friends, aided by a couple of unscrupulous or conceitedly whimsical medical persons, might depopulate any asylum, and with impunity expose individuals to outrage and property to ruin, for no penalty attaches to an error in judgment as to the harmless nature of the lunatic set at large. Safety is not ensured by the proviso that the medical persons certifying harmlessness must be approved by the Commissioners, for it would be a most invidious step for the Commissioners to take to disapprove of any duly qualified medical man, and practically they would have to approve of every member of the profession who had not been shown to have behaved disgracefully in a professional respect. Any two doctors then would be in a position to liberate any lunatic when moved thereto, by any indifferent person, who may never have seen the lunatic, who may be actuated by a desire to annoy his friends and relations, or by a general antagonism to the lunacy laws. Any lunatic may institute any number of inquiries into the cases of any number of incarcerated lunatics, for the person obtaining the order of the Commissioners under this section does not require to be of sound mind, and any lunatic with a large circle of anxious acquaintances might be examined by a hundred brace of doctors in succession, for no limit is put to the number of orders that may be obtained from the Commissioners in any particular case, and they would have to go on issuing them as long as they were asked for. Does Mr. Dillwyn imagine that any lunatic asylum could be conducted under the conditions which would be created by this section? If he does so, he knows marvellously little of the subject on which he has undertaken to legislate. No respectable medical man would, for a day, consent to conduct an asylum in which he would have to be perpetually on his defence against all comers, in which his professional judgment was liable to be called in question at any moment and set aside by two irresponsible medical men with no experience in insanity. The department of private lunacy practice has been already made sufficiently irksome and disagreeable. The best men engaged in it desire to have done with it, and young men of ability and spirit, unless drawn into it by family ties, decline to enter it. The unfortunate lunatics, of course, suffer. It has been left for Mr. Dillwyn, however, to propose the utter ruin of a department of practice with which great names have been associated, and to hand over the insane of the higher classes to such needy and inferior persons as will submit to his ignominious regulations.

Section 16, which provides for the licensing of attendants, must be nugatory, or detrimental. It empowers the Commissioners to grant licences to attendants on the production of a certificate from the superintendent of an asylum that they have been employed by him for a period of not less than six months, and that he considers them qualified to undertake the care of lunatics. The Commissioners would probably see fit not to exercise the power thus conferred on them, and if they did do so their licences could not possibly be worth more than the certificates on which they were founded. They would simply amount to official records of the registration of these certificates, which, of course, would be of very varied value, according as they were obtained after long service in a large, well-organised lunatic hospital, under an able and energetic medical superintendent, or after six months' shoe-blacking in a small licensed house, and under a medical superintendent whose chief forte was smoking. But by the public all licensed attendants would be rated alike, and thus utterly ignorant and incompetent persons would obtain employment as readily as those who were well trained and expert. Far better than such licences are the testimonials which attendants now produce, which admit of infinite variations of light and shade, and which are given under a sense of personal responsibility. If attendants on the insane are to have licences that will really imply experience and certain moral qualities that are almost essential in those who are to have the care of lunatics, they must go through a period of probation much longer than that contemplated by Mr. Dillwyn, for two years is the shortest time in which they can learn their business, and they must have their proficiency in their work tested by examination, and their good dispositions established by the testimony of the officers under whom they have served. And of course, attendants who have gone through such education and trials will expect to be amply remunerated, and will probably be disappointed in their expectations. The true way, the only way to secure efficient, kindly, self-controlling attendants, is not by conferring sham licences upon them, but by paying them liberally and supervising them vigilantly. When by a generous scale of remuneration, by considerate attention, and assured retiring allowances, the service is made attractive to persons of a higher social status than that from which attendants are now drawn, there will be no need for licences. The scraps of paper that are required to improve the service on the insane are not licences, but bank notes. This does not seem to have occurred to Mr. Dillwyn.

A more illusory Bill than that we have been examining we have rarely encountered. It builds up bulwarks of pasteboard, and is honeycombed with defects. Should it by any unhappy chance become law, a sad blow would be administered to the true interests of the insane in this country.

## THE PROVIDENT DISPENSARY SCHEME.

As we intimated last week, a scheme has been drawn up by the Provisional Committee of the Metropolitan Provident Dispensaries Association, which has for its object the arranging on provident principles for the ordinary medical treatment of the industrial classes in due relation to the existing hospitals of London. The defects of the present mode of giving indiscriminate medical relief to all who care to have it are that, whilst about half the working men of London belong to friendly societies, the greater part of which provide medical assistance in times of illness for their members, on what is called the "club doctor system," their wives and children are totally uncared for, and are therefore relegated to the hospitals, the out-patients, departments of which are crowded by them. Correctly speaking, the motley group seen hanging about the doors and waiting-rooms of hospitals consist partly of the wives and families of the working classes, of the poorer class of clerks, and small tradesmen, but none of whom are paupers, or who can rightly claim to be treated as such, so it has come to pass that about one-fourth of the vast population of London are receiving gratuitous advice and medical treatment; it must, however, be acknowledged that this, for the most part, is of a very imperfect kind. It might have been thought that the delay and hardships inflicted upon the crowd of applicants would have acted as a deterrent; this appears not to be the case; and whilst the patients obtain only a fractional part of attention from the overworked medical officer in attendance, the cry is, 'They come,' prepared to brave the consequences of overcrowded and often infectious waiting-rooms, together with the serious loss of time which the system entails upon them—the equivalent of a money value often greater than that of consulting a medical man at his own home.

The arrangement proposed by the Provisional Committee to meet the evils of gratuitous medical services is that persons of every class who are intermediate between those who can pay the ordinary professional fees and the pauper, who is amply provided for under the Poor-law, should become members of provident dispensaries, on a co-operative mutual assurance principle, whereby they can obtain advantages similar to those possessed by the rich. Those who can attend at the "district dispensary" will have advice and medicine without undue delay; those who cannot will be assisted and treated at their own homes. Every member will also have an opportunity of selecting his own medical attendant, who will advise the family in all that concerns the prevention as well as the cure of disease. This is not only a perfectly feasible scheme, but in every way to be commended, since the average amount of sickness is tolerably uniform, and if it cannot be so exactly estimated as that of the average number of deaths at a given period of life, nevertheless a fairly accurate estimate can be made of the amount of sickness which is likely to occur amongst a given number of persons of known ages, occupations, and conditions. That calculations of sickness cannot be based on such precise laws as those of deaths is due to the simple fact that death is absolutely certain, and can be estimated accordingly, whilst sickness is more or less a matter of degree and opinion. Nevertheless, it is perfectly true that the average percentage of persons who will be visited with illness may be tolerably accurately calculated upon in advance from year to year. In the provident dispensary movement, then, the wage-earning classes, and those who cannot afford to incur the responsibility of a doctor's bill, may exercise their thrift and show themselves as above partaking of the doles of charity, for it must be a small minority of the working population of London who cannot afford to pay five or ten shillings a year to enrol themselves members of a district dispensary. From a political or practical point of view, it does appear quite worth while, as Lord Derby said, "to impress upon the working classes the duty of increased forethought and providence, as a matter not only of personal, but of national obligation." To the provident dispensary, then will be assigned its proper work, that of doing the ordinary work of the family doctor, whilst the hospital will act as the consulting physician or surgeon in all serious and difficult cases, for those who cannot afford to pay consultation fees, and it will also provide in-patients' treatment with the advantage of constant professional attendance and skilled nursing for the more urgent cases; so that whilst on the one hand the out-patients' departments of the hospitals will no longer be thronged with trivial cases, on the other those dispensary patients requiring a second opinion or clinical treatment will be at once relegated to the hospital best suited to afford them relief.

For carrying a scheme of the kind into effect, a preliminary outlay must be made; and the due remuneration of the medical officers provided for; after the dispensaries have obtained a fair start, and obtained their respective complements of members, there will be no difficulty on this score. But as there will be the necessary expense of providing buildings and other important accessories for carrying on the work of the provident dispensaries, it is proposed to form a Central Committee or Council, which shall be charged with a superintending duty throughout the metropolis, and to whom we may look to furnish every necessary accommodation, and on the most economical scale consistent with the objects in view.

The difficulty of the scheme does not consist so much in the manipulation of details as upon whom the onus of providing the outfit and other expenses necessary for founding provident dispensaries should be thrown. We certainly think it should partly fall upon those who are to benefit by them; otherwise, as it has been justly remarked, we should run the risk of destroying the self-respect and independence of those who will be partakers. The reform of the present system of medical relief should certainly be based upon the action of the friendly societies, societies including the self-governing branches of the larger organisations, such as the "Foresters" and "Oddfellows," which include, it is believed, about half the working population of London.

The Committee think that certain city parochial endowments might be pressed into the financial part of their scheme, and that some portion of dormant and misappropriated capital, derived from the bequests of ancient benefactors, might well be applied to furnish a solid basis for the work of self-supporting institutions of the kind now proposed.

Provident dispensaries will, under any circumstances, be a great gain to the medical profession, who will reap some remuneration in exchange for an immense amount of hard work that has been hitherto performed gratuitously. An enormous number of persons who now receive entirely gratuitous advice in the out-patient department of all our hospitals will be brought under contribution by it. The medical officer will be sure of making no bad debts, all payments being made not to the doctor direct, but to the dispensary. His popularity and usefulness in his own immediate neighbourhood will be increased, and his general position enhanced by the arrangements proposed by the Provisional Committee of the Metropolitan Provident Dispensaries Association, and we heartily wish the new scheme every success.

◆

## THE LATE ELECTION OF MEDICAL OFFICERS AT THE NATIONAL HOSPITAL FOR PARALYSIS AND EPILEPSY, QUEEN SQUARE, LONDON.

It is popularly supposed that the managing committee of an hospital exists as a committee in order to watch over the interests of the institution which the founders have bequeathed to its care. It might also be presumed that among those interests not the least in importance would be the choice of fitting medical officers, and that every hospital committee would be guided in such choice by the known antecedents of the various candidates, by the relative values of their testimonials, and last, but not least, by the opinion the existing members of the staff might express as to the fitness of any particular candidate.

It seems, however, that there is at any rate one hospital in London the committee of which is ready on occasion to make the interests of the hospital entirely subordinate to the puerile gratification of unreasoning prejudice. That unfortunate hospital is known as the National Hospital for Paralysis and Epilepsy, Queen Square, and was the first founded in England for the treatment of diseases connected with the nervous system.

Briefly, the facts of the case are these: Dr. Allen Sturge, who lately offered himself as a candidate for a vacant post on the staff of this institution had devoted himself during the years 1875-76 entirely to the work of the hospital, first as registrar, afterwards as resident medical officer and registrar combined, and had commended himself to the warmest approbation of both the committee and the staff. At the staff meeting which preceded the election, five out of the six members of the staff being present, Dr. Sturge was unanimously recommended to the managing committee for the *senior* of the two vacant assistant-physicianships. The other candidates, it should be said, had neither of them been connected with the hospital or done any work in the department of nervous diseases. But there remained one stubborn fact, which in the eyes of the National Hospital Committee far outweighed all Dr. Sturge's antecedents and testimonials, and made the opinion of the staff count as dust in the balance. He is married to a lady of his own profession! and therefore can no longer be expected to do his work with the same zeal and efficiency; indeed, he must now be looked on as altogether incompetent to treat those diseases which for five years have formed the chief subject of his studies, or to be entrusted with the responsibilities of a Physician at the National Hospital. So reasoned the Committee, and after a series of meetings extending over three weeks—when, if we may judge from the sequel, some faint shade of doubt as to the justice and propriety of the act they contemplated, and the verdict of the public thereon, must have crossed their minds—they decided to request Dr. Sturge to spare them the onus (or shall we say the odium?) of refusing the one candidate possessing every qualification for the appointment under consideration, and they deputed one of the staff to call on him and suggest that he should withdraw his application. This generous suggestion on the part of the Committee was not accepted, and the Committee of the National Hospital, who thereupon elected two of the junior candidates, have now to bear the odium of an act equally discreditable to the intelligence and to the moral sense of its members.

We trust that neither the medical profession nor the public will let this matter drop without the strongest protest. The staff of the hospital, composed as it is of some of the highest names in our profession, cannot, consistently with its own honour and dignity, submit quietly to such treatment from a Committee which is in reality its debtor. The public has already begun to be roused, and the first idea of many will be that an hospital so grossly misgoverned cannot expect its subscribers to continue their support.

◆

## THE LOCAL GOVERNMENT BOARD AND THE DRUG SUPPLY OF IRISH UNIONS.

Some months ago we called attention, not for the first time, to the subject of the supply of drugs to the unions of Ireland. We then made brief allusion to the form of tender authorised by the Local Government Board. We shall now place before our readers a little more information about this document. There are 649 articles of the materia medica enumerated in it, and of these 109 are not in the British Pharmacopœia, but have been retained from antiquated editions of the Dublin one. They are such articles as *Linimentum Aeruginis*, *Aloe Hepatica*, *Extractum Fuliginis*, and the like. We have further found about two hundred articles which are useless for, or unsuited to, dispensary practice. Thus nearly half the list might be cut off at one stroke, and after that it might very well be further pruned of redundances.

But if the tender-form errs in excess its errors in defect are no less obvious. It contains none of those convenient forms for dispensing which have been recently introduced into pharmacy. As the tender we had under examination was a copy of one which had been accepted by a board of guardians, and the prices were marked, we have compared them at some length with the published price list of the London General Apothecaries' Company. This company is essentially a co-operative association of medical men, the object of which is to supply the shareholders with medicines of good quality at the lowest prices. The list prices are subject to a discount of 12½ per cent. to shareholders, and the profits are such as to pay 8 per cent. on the capital. It may, therefore, be concluded that the prices fairly represent the market value of good drugs. Now we have compared the prices in the General Apothecaries Company's lists of 87 articles in constant use with the prices of the same articles in the tender above referred to, and the latter were *thirty-seven per cent.* below the other. The price of the tinctures was *forty* per cent. lower.

It is impossible, without using language which would be "unparliamentary," adequately and truthfully to characterise the conduct of a governing body which can tolerate for years such a state of things as this examination reveals. We have in this journal dwelt, *usque ad nauseam*, on the effect of the apathy and obstructiveness of the Local Government Board upon the sanitation of Ireland; but here is revealed, if possible, even a worse dereliction of duty. Here is the care of the supply of medicines on whose purity depends the efficiency of the entire Poor-law Medical Service relegated to some subordinate who manifests total ignorance of the changes which have taken place in the Pharmacopœia during the last thirty years, and who has not the remotest idea of what the requirements of dispensary practice are, while worse than all, year after year medicines are supplied of the quality represented by such scandalous contract prices as we have given a sample of.

When articles of food and clothing are tendered for, samples are laid before the board of guardians for inspection, so that there is some check upon the dishonesty of contractors, but the quality of the medicines is utterly uncontrolled. They may be anything, and we believe that in the majority of instances they are valueless as therapeutic agents.

We would direct the attention of our readers to a paper by Dr. Wallace, of Parsonstown, in another part of this journal, "On the Supply of Pure Drugs." He treats of the subject from a dispensary officer's point of view, and his suggestions are well worthy of adoption. But the matter is one which calls urgently for the pressure of public opinion to be put on the Local Government Board. It is pitiful when a public body must be goaded on to do its work and fulfil its obligations. But thus it is. One cannot help asking, *What might have been?* had the Board risen to the height of their magnificent opportunity for benefiting Ireland.

But we have not done yet with our detail of the miserable mismanagement of Irish affairs. It might have been expected that at least the Adulteration of Drugs Act would have been put in motion to bring to light the wholesale adulteration of drugs which must be going on. That Act authorises the examination of drugs by the "county analyst." But when we come to inquire, it turns out that in some twenty-eight instances that public functionary is represented by a ubiquitous professor who is equally at home in chemistry, analysis of food and medicine, and sanitation. His greatest admirers may, however, be pardoned for questioning whether even his versatility is capable of doing justice to the analytical duties of nearly the whole of Ireland.

# Notes on Current Topics.

## The Surgeoncy to the County Dublin Prison.

Dr. William Carte, J.P., Surgeon to the Royal Hospital, which is the Chelsea Hospital of Ireland, has been appointed to the Surgeoncy of Kilmainham Gaol, vacated by Dr. Rutherford Kirkpatrick.

The appointment will be generally approved, for Dr. Carte is in every way fitted for the discharge of the duties—has the advantage of living quite close to the gaol, and has acquired, by his services in the army and in the Royal Hospital, an undoubted claim to any public promotion within his department. The circumstances of the appointment are, however, peculiar, and as an illustration of the very eccentric proceedings of the newly constituted General Prisons Board for Ireland, are worth recapitulating. Some two years since, Dr. Kirkpatrick asked for leave, and named Dr. Henry Fitzgibbon as his *locum tenens*, which arrangement was approved by the Prisons authority, and Dr. Fitzgibbon accordingly entered on the duties, and performed them with the full concurrence and approval of those authorities. After a time Dr. Kirkpatrick found it necessary to resign his office, which he did by letter, to which communication he received, we believe, no answer. He, however, did not resume the duty which Dr. Fitzgibbon continued to discharge, and for which he was paid over Dr. Kirkpatrick's head. After a long time, Dr. Fitzgibbon asked for leave and suggested a *locum tenens*, upon which the General Prisons Board wrote to say that the application should be made to Dr. Kirkpatrick, the medical officer of the prison. That gentleman immediately repudiated any responsibility in the matter, pointed out that he had resigned long previously, and had never since then done the duty or received the pay, and declined to give or refuse the leave asked by Dr. Fitzgibbon. Thereupon the question dropped, and things went on as before, Dr. Fitzgibbon doing the work and receiving the salary, but not being regularly appointed.

As it afterwards appeared, the Prisons Board and the Treasury were, during this period, engaged in a snarling secret correspondence over the matter. The Treasury, with the insolent bureaucracy for which it is noted, refused positively to appoint *any* surgeon to the gaol, and wrote a letter to the Prisons Board, in which it set forth in so many words and without circumlocution that it was its intention to force the City Prison medical officers to do the County Prison work (no salary being at any time proposed for such duties); that it was aware that the Act of Parliament protected these officers from such imposition of extra duty, but that, nevertheless, those officers were to be informed that—if they refused the new and gratuitous functions—they would be dismissed from their present offices.

It will hardly be believed that a public department should promulgate such an order, but we can vouch that they did so. To such a letter these officers sent a reply which, we believe, threw upon the Prisons Board the onus of carrying out their threat if they dared.

They did *not* dare; but not long afterwards they promulgated an order fixing the salaries of prison surgeons in Ireland, and setting down that of the Kilmainham surgeon at £100 a year, this being the first hint given by the Board of their intention to pay any salary at all for the medical service of the County Dublin Gaol.

All this time Dr. Fitzgibbon continued to perform the duty and receive the pay until he was—without preface or parley—informed that Dr. Carte had been appointed to his office.

Was ever such a story of departmental incompetency, confusion, and bureaucracy? It suggests doubts of the existence of a head in the Prisons Board, and confirms the conclusion that there is no such thing as a fair—just—business-like policy in that department.

While we adhere to our opinion, Dr. Carte is in all respects well suited for his new office, we sympathise warmly with Dr. Fitzgibbon in the scandalous treatment to which he has been subjected. No private employer would either desire or dare to treat his *employé* in this way, and inasmuch as we fully believe that it is the aggregate of these transactions which makes up the sum of the unpopularity of a Government, we look upon the frequent repetition of such display of arrogant imbecility as the premonitions of a coming downfall.

### The late Thomas Bell, F.R.S.

On Saturday, the 17th inst., died one of the best known of the English biologists who date their scientific studies from an association with medicine. The late Thomas Bell was for a long time in the enjoyment of extensive practice as a surgeon-dentist, and occupied the position of Examiner in Dental Surgery in the Royal College of Surgeons of England. He became Member of that corporation in 1815, and honorary fellow in 1844. His professional studies were prosecuted at Guy's and St. Thomas's Hospitals, at the former of which he was some time Dental Surgeon and Lecturer on Dental Anatomy. It is, however, as a zoologist that Bell's name will be longest remembered, his treatises on "British Reptiles" and "British Quadrupeds" being even yet standard works. In 1832 he was made Professor of Zoology in King's College, having four years previously had conferred on him the distinction of election into the Royal Society. Of this body he was Secretary from 1848 to 1853, and from 1853 to 1861 was President of the Linnæan Society. The later years of Professor Bell's life were passed at the house immortalised by Gilbert White, "The Wakes" at Selborne, the place having been sold to him by the great nieces of the naturalist. Bell's latest work was a sumptuous edition of the "Natural History of Selborne," he having attained his eighty-fourth year on its publication. Of his more technical writings the best known is a volume on the "Anatomy and Diseases of the Teeth."

### Westminster Hospital.

H.R.H. the Prince of Wales presided at a dinner held on Saturday week at Willis's Rooms in aid of a fund for the improvement of parts of Westminster Hospital. That this is a very necessary undertaking is apparent to all who are acquainted with the arrangements of the medical school attached to the institution, and the out-patient rooms of the hospital itself. The initiative set by Charing Cross Hospital may with advantage be followed at Westminster, for the close contiguity of the school buildings to the wards of the charity cannot be productive of anything but injurious consequences. Already some £2,500 has been subscribed towards the amount necessary. We trust there may be no desire to obtain an extravagant sum of money before the changes so pressingly necessary are commenced.

### Death of the West Kent Coroner.

Mr. W. Carttar, the Coroner for West Kent, died on Friday morning last, after a lingering illness, at his residence, Blackheath Road, Greenwich. Mr. Carttar had been in office over forty years. He presided over the inquiry into the Penge murder, and also over that held after the disastrous Princess Alice collision on the Thames. The late coroner was not a medical man, but a member of the legal profession.

### Novel Antisepticism.

Dr. R. J. Levis, Surgeon to the Pennsylvania Hospital, claims, in a paper contributed to the New York *Medical Record*, to have invented an antiseptic method of dressing wounds. Apparently he uses no spray or other protective, either during or after operation, but having inserted a drainage tube and secured the flaps of the wound, he next, with a Davidson's syringe, "washes out the wound very thoroughly with carbolised water, forced in through the openings between the sutures. . . . . The water, which contains carbolic acid in the proportion of one to forty, is pumped in until it gushes out between the sutures and carries with it all the clots and bone dust that may still lie between the flaps. The end of the syringe is inserted into various openings successively, until the distended cavity is thoroughly cleansed and filled with the antiseptic solution. The water is not pressed out, but a piece of lint, saturated with carbolised oil, is applied, and a firm bandage adjusted. By this means putridity and suppuration of the wound are prevented as much as possible, for decomposing clots are prominent factors in preventing union and causing suppuration." Dr. Levis claims that he is able to produce the best results with this method, a case of amputation at the middle third of the thigh so treated having recovered sufficiently to leave hospital in two weeks. We imagine many old country surgeons will be not so entirely unfamiliar with the rough-and-ready antiseptic treatment described above; and equally we incline to think those who resort to it will not be reckoned by the antiseptic practitioner as being members of *his* school. That Dr. Levis can obtain one good result by his method should be taken as peculiarly fortunate by him. That he will be often successful we venture to doubt, unless he has omitted to detail other essential precautions observed by him.

### American Opinion of the Professional Status in England.

In a recent number of the *Philadelphia Medical Times*, a leading article is devoted to considering why the status of the medical man in England is lower than that of his brother across the Atlantic. The conclusion arrived at is that medicine will never be able to compare favourably with the other learned professions until it is placed on a basis similar to them—that is, "Until there are medical lords who have a right to speak upon the floor of the House of Lords, and who shall exert an influence on the decision of all questions of State medicine, comparable to that of the law lord in legal questions." Only then, concludes the *Times*, can the medical profession of Great Britain "expect to control the Governmental action as they do in America, or be recognised by the mass of Englishmen as entirely the peers of members of the other professions." Whatever truth there may be in these remarks, we are ourselves of opinion that the adventitious aid of handles affixed to the names of a few will not materially advance the general professional dignity. One of the most powerful engines in this direction would be a union among medical men by which common aims would be advanced and the elevation of the whole class be secured. To the want of cohesion among the members of our profession, and the absence of any centralisation agency, is due much of its inherited weakness.

## The Irish Elections in their Medical Aspects.

We referred last week to the intention of some of our medical brethren to compete for seats in England and Scotland, and we have, to-day, something further to say to Irish medical electors.

To the medical sections of the constituencies of Kildare, Galway, Longford, and Leitrim we would especially appeal for their warm support for Mr. Meldon, Mr. Mitchell-Henry, Dr. Ward, Mr. Errington, and Dr. Brady. Mr. Meldon, though not *one* of ourselves, we put in the foremost rank, as deserving of the most active exercise of interest in his behalf by every Irish medical man. To his aid the Irish Medical Association is indebted for almost all that it has been able to do in the way of Poor-law medical reform in Parliament, and we understand that the Council of the Association has, last week, indicated their appreciation of Mr. Meldon's services by a formal resolution recommending him to the medical electors of his constituency. It was Mr. Meldon who stood sponsor for the Vaccination Act of last year, who conducted our parliamentary proceedings about the Public Health (Ireland) Act, and who now has charge of the Registration of Births and Deaths Bill, and his advice and assistance have been—we can say with truth—invaluable to the Irish Medical Association, while it was most kindly and willingly given on all occasions.

Mr. Meldon has manifested, to our knowledge, great legislative ability, which of itself ought to entitle him to the suffrages of his constituency, and we earnestly hope there will not be found a medical voter in Kildare either reticent or lukewarm in his support of Mr. Meldon. In medical affairs Mr. Errington has also displayed great interest and unwearied industry, and has taken up the case of the Irish prison surgeons with warmth, and it would be a serious loss to the medical profession if any circumstances prevent his return for Longford. Mr. Mitchell-Henry, Dr. Ward, and Dr. Brady have not identified themselves with medico-political legislation to as great an extent as Mr. Meldon or Mr. Errington, but nevertheless it is of great importance that they should retain their seats, because they have always willingly helped us when their aid was desired and asked, and their co-operation will be greatly needed in the coming Parliament. Dr. Brady has more than once sacrificed his time and his convenience to do the work of the profession in Ireland and of the Irish College of Surgeons, and is in every way deserving of support.

We earnestly trust that our medical brethren will have the courage of their convictions in the coming contest, and will keep before their minds the interests most near to their hearts. What can it matter to them the political views of a member, comparatively to the imperative necessity of maintaining and reinforcing the parliamentary influence of our profession?

Let Irish medical voters not forget that Bills are before the House which will, if passed, protect them from the abuses of Poor-law medical relief, give them fair superannuation and an excellent registration system, and that they are *bound* to secure adequate support for these measures by voting for and aiding the parliamentary supporters of our profession, no matter who else may seek their suffrages.

## The Dental Profession in France.

We are glad to see that at last there seems a fair prospect of an improvement in the dental branch of the profession in France. It has long been a matter of wonder why in a country where the education and status of the medical profession generally leave little of serious importance to be desired, dentistry has always been ignored by medical authorities, and has been relegated by common consent into the hands of charlatans. The number of dentists in France holding a diploma indicating professional education is extremely small, and this number is mainly composed of foreigners—Englishmen and Americans. We also believe that there is no school of dentistry in France, and lectures or instruction on the subject are, as a rule, not provided at the medical schools or hospitals. Thanks to the efforts, in the first place, of Dr. Mordaunt Stevens, of Paris, an old student of the Dental Hospital of London, this deplorable state of things appears likely now to undergo a change for the better. A society has been formed, styled "La Société Syndicale des Dentistes," to which many of the most respectable French practitioners have united themselves, and this society will have the object of elevating the profession, of removing the abuses which exist, and of placing dentistry in France upon an improved footing, such as it has taken in this country, and which its importance to the public makes it urgently desirable it should occupy. We wish all success to this new society, and we shall watch its progress with interest and sympathy.

## A New Anæsthetic for Dental Surgery.

At the last meeting of the Edinburgh Odonto-Chirurgical Association, Mr. W. B. Macleod brought under the notice of the Society a new combination anæsthetic which he had been using for some time past in his private practice with very successful results. It consisted in combining the administration or the exhibition of ethydene dichloride in nitrous oxide gas. The manner of administration was simple. It consisted solely of placing a small piece of sponge, retained in position by a clip within the way-tube or supplementary bag of the nitrous oxide inhaler, leaving sufficient space on each side of the sponge for the free passage of the nitrous oxide into and out of the bag. Only a very small quantity of ethydene dichloride was required, viz., about half a drachm. The time of inhalation to produce anæsthesia measured from 60 to 70 seconds, and the time of complete anæsthesia—during which time the sensation was said to be more profound and agreeable than when induced by nitrous oxide gas alone—was from 1½ to 2½ minutes, which embraced a period of time sufficient to enable most of the operations required in dental surgery to be comfortably performed. He further mentioned that in all cases in which he had used this anæsthetic, upwards of 16 in number, there had been a complete absence of sickness, and only one case in which there might have been said to be the slightest approach to stertorous breathing. The pulse was slightly more accelerated than normal, but was full and strong, and there was the absence of lividity which renders the administration of nitrous oxide so disagreeable, and in some cases repulsive, to the onlooker, the lips alone on the removal of the face-piece presenting in any case—and that only occasionally—the faintest appearance of lividity. It had also this decided benefit over the single administration, that it produced a relaxation of the muscles, so contrary to the almost spasmodic rigidity induced by nitrous oxide. The society resolved to experiment with this anæsthetic.

## Abuses of Charity Voting.

We regret to observe that the *Exchange and Mart*, which journal, as our readers may remember, had announced its intention of establishing a department for the sale of what is called "charity" votes, persists, in spite of our remonstrance, in encouraging this nefarious traffic, and is about to open the market for votes in its next issue. If the *Exchange* is not already convinced of the impropriety of engaging in a traffic which itself admits to be objectionable, we cannot hope to influence it by pointing out that the giving of a vote to an undeserving object is equivalent to the stealing of the money of the "charitable" institution upon which that undeserving object is quartered perhaps for life. But we hope that the lesson will not be lost upon the managers of *soi-disant* charities, who will now have no excuse for pretending to be ignorant of the means by which the benefits of their institutions are bought and sold. They will have no difficulty in ascertaining the extent of this vile traffic from the pages of the *Exchange and Mart*, and, if they continue to permit the prostitution of their charities to undeserving objects, they will deserve the "scourge of small cords" which was once used with those who made our "Father's house a house of merchandise."

## Perinephric Abscess opened by Thermo-Cautery.

At a recent meeting of the Paris Hospital Medical Society (*Le Praticien*), Dr. Duguet brought forward the case of a young man, æt. 36, admitted under his care in December. He had for twelve days been suffering from fever, emaciation, loss of appetite, and violent pain in the right renal region. On his admission his face was drawn, temperature 39° C. (102·2° F.). There was fixed pain without thickening or swelling, in the right lumbar region. Fifteen leeches were applied without relief. On January 2 swelling and œdema were evident, and on the 12th fluctuation was manifest. Local anæsthesia having been produced by cold, an incision seven to eight centimetres long was made by means of the thermo-cautery parallel to the last false rib on the right side, and one centimetre below it. On attaining a depth of six centimetres there flowed from the incision about half a litre of thick pus. The general symptoms rapidly improved, and cure was complete in less than 40 days from the beginning of the trouble. By a singular coincidence two other precisely similar cases were admitted at the same time to the Tenon Hospital. These two cases were evidently caused by cold and fatigue, but a similar etiology could not be proved for the above case. These two other cases were also opened by means of the thermo-cautery, and recovered without complication.

Mr. Christopher Heath, F.R.C.S., of University College, has been elected Chairman of the Board of Examiners in Anatomy and Physiology at the Royal College of Surgeons of England,

## The Physician to the Queen in Ireland.

Her Majesty has selected Dr. John Banks for the distinction of Physician to the Queen in Ireland, vacated by the death of Sir Dominic Corrigan, and Her Majesty's choice receives the entire approval and concurrence of the profession. Dr. Banks has long held a very high rank as a physician in Dublin, and his relation to the Richmond Lunatic Asylum as its Visiting Physician has secured for him a special repute as an authority in mental disease. He occupied for many years the Professorship of Practice of Medicine in the School of Physic of the University of Dublin, and still retains his appointment as Physician to the Richmond, Whitworth, and Hardwicke Hospitals. Dr. Banks has served the office of President of the King and Queen's College of Physicians, and is a Senator of the Queen's University, and, in the profession, there is perfect accord as to his just claim to the distinction which Her Majesty has conferred upon him.

## The Health of Ireland.

The mortality during the week ending March 13th in twenty large English towns, inclusive of London (in which the rate was 20·5), was equal to an annual average death-rate of 21·4 per 1,000; in Glasgow the rate was 26·3; and in Edinburgh, 17·9.

The average in the sixteen principal town districts of Ireland was 34·3, the respective rates for the several districts being as follow, ranging in order from the lowest to the highest:—Sligo, 15·0; Newry, 17·6; Queenstown, 18·0; Dundalk, 19·2; Galway, 21·1; Limerick, 29·4; Belfast, 31·7; Drogheda, 33·9; Dublin, 35·0; Lurgan, 37·0; Londonderry, 37·0; Wexford, 37·8; Waterford, 39·1; Kilkenny, 42·1; Cork, 43·0; and Clonmel, 90·1. A death from small-pox was registered in Belfast, where also 5 more deaths from whooping-cough were recorded. There has been a further decline in deaths from scarlatina in Cork, only 4 having been registered during the week. At Drogheda measles is epidemic.

## Death from Hydrophobia.

In Rostrevor, on Saturday week, a man, named Peter Neill, æt. 38, died in his own house from hydrophobia. Last harvest the deceased, while herding cattle, was bitten by his dog on the thumb, and on Wednesday he was taken ill, and died on Saturday in dreadful agony.

## Royal Belgian Academy of Medicine.

The *Progrès Médical* gives the following list of the prize questions of the Royal Belgian Academy of Medicine:

1. The history of the diseases of the nervous system, especially epilepsy: April 1, 1880.
2. The material and psychical effects of alcoholism, both on the individual and his descendants: July 15, 1880.
3. A comparative investigation of rickets, osteomalacia, and *cachexie ossifrage* in the domestic animals: May 1, 1881.
4. The nature and influence of innervation on the nutritiyn of tissues: January 1, 1881.
5. The influence of desiccation, used as a means of con-

servation, on simple medicinal substances of the vegetable kingdom: February 1, 1882.

6. The influence of animated germs in the etiology of diseases: January 1, 1883.

### The Torbay Infirmary.

A SERIOUS disturbance has occurred at the Torbay Infirmary, in Devonshire, ending in the resignation of the resident surgeon, who refused to submit to the dictation of the lay officials respecting the technicalities of his duty. Attempts were made to interfere with the authoritative action of the medical officer in respect to the treatment of the patients in his charge, and the consequences have been somewhat similar in kind to those which have followed lay opposition at Guy's Hospital. We propose to lay an analysis of the whole occurrence before our readers at an early date, for the instance points afresh to the impropriety of reposing any authority over the professional conduct of hospital charities in the hands of the non-professional and purely business staff.

### Food for Semi-starved Children in Ireland.

MRS. LALOR, of Rutland Square, Dublin, has issued a circular to the leading members of the profession in Ireland, in which she appeals for funds to enable her for the present to improve and increase the dietary of poor children throughout Ireland.

The appalling cases Mrs. Lalor has witnessed of little children dying out slowly and patiently through a course of semi-starvation on insufficiently nourishing food, and the difficulty experienced in bringing some round from their lethargy and inability to digest any solid food, has led her to consider what a grave question arises for the future of Ireland in the survival of the strong ones after having passed through a crisis of six months' insufficient diet on Indian meal alone, which will develope many diseases to which children, through their scrofulous tendency, are peculiarly liable, and which are already showing in some districts.

Mr. Lentaigne, the Inspector-General, states the average school attendance this last quarter has lessened 37,000, "through want of clothes and illness, consequent on distress." If not saved *at once*, these future fathers and mothers of Ireland can never develope the healthy brain and muscle to fight later the battle of life.

Mrs. Lalor proposes to collect funds to give these little ones, until the end of June, one good nourishing meal of bread and milk, or ox-head soup and bread, or oatmeal stirabout and milk, according to the districts, and by giving this in connection with the schools, Catholic and Protestant, wherever *real*, undoubted distress exists, it will ensure education as well as food.

This scheme has the hearty approval of Her Grace the Duchess of Marlborough, of the Lord Mayor, also of the *New York Herald* Fund. They are now considering how to assist it through their existing organisations.

Pending further arrangements, Mrs. Lalor started 1,000 children in the most distressed districts, and for £20 a week she can feed 1,000 children. We wish her enterprise every success.

### Death from Chlorine Inhalation.

AN inquest was held last week in Dublin by the City coroner, on the body of a man who had been suffocated by the fumes of chlorine gas, while the process of disinfecting his bedroom was being carried on. It appeared from the evidence that the deceased, who was fifty-one years of age, had been for some time past confined to bed by illness, and was of weak intellect. A medical order having been obtained by the sanitary authorities for the disinfection of his room, they proceeded to his residence, having delayed the execution of the order for a few days owing to deceased's illness. They arrived during the absence of the sister, who lived with him. They brought him out of the room into the hall, and left him standing there while they disinfected the room. They closed down the window, and when they had finished they told him it would be certain death if he went into the room for six hours. He promised he would not, but no sooner had the man left than he ran into the room and pulled down the window, and immediately afterwards was seen standing at the door suffocating.

### The Naval Medical Service.

AT the recent examination, held in London, five candidates presented themselves for admission to the Medical Department of the Navy, and a contemporary informs us that even these five failed to convince the examiners o their competence for the Service. After this, there surely can be no question about the necessity of an inquiry into the best means of making her Majesty's Naval Medical Service more attractive to fully competent members of the profession; and we are glad to hear that such an inquiry is about to be instituted.

### Treatment of Neuralgia by Aconitine.

IN a recent number of *Le Praticien* is a *résumé* of a work by Dr. Oulmont, physician to the Hotel Dieu, on the use of aconitine in neuralgia. Dr. Oulmont says that aconitine succeeds perfectly in certain forms of essential facial neuralgia—that is to say, not connected with other lesions, not markedly intermittent or periodic; in fact, congestive neuralgias, as Dr. Gubler calls them, generally supervening as the result of cold. In these cases aconitine effects cures with great rapidity in two or three days. He has seen a case of facial neuralgia seven days old, without well-marked periodicity, which had resisted sulphate of quinine, yield instantaneously and definitively to one quarter of a milligramme of nitrate of aconitine.

Success is more marked and more rapid in recent than in old neuralgias. He can mention, however, cases which had lasted one month, two months, and five years, which have been cured; the first in seven days, the second in three days, and the third in three weeks. Aconitine is not without action in secondary neuralgia and hyperæsthesia, such as is seen in dental caries, caries of the temporal bone, internal otitis, paraplegia, &c. Acute articular rheumatism treated by aconitine has given good results. In four individuals, to whom the remedy was given in the dose at first of half a milligramme, rising to one and then one and a-half milligrammes, cure was effected once in eight days, and the second time in ten days. In the other cases cures were also effected, but only on the fifteenth and eighteenth days, and the dose of the remedy was raised gradually to two and two and a-half milligrammes. In neuralgia of the trigemini, Gubler says the effects are truly marvellous.

Dr. Oulmont concludes that aconitine is a well-defined remedy, which acts in man surely and regularly, but on account of its energy it must be used in very small doses and at long intervals. Where neuralgia is accompanied by well-defined intermittent and periodical attacks, it is necessary to combine quinine with the aconitine.

## The Structure, Development, and Significance of Tubercle.

At a recent meeting of the Academy of Sciences of Paris (*France Médicale*) MM. Kiener and Poulet made a communication of researches on the structure and development of tubercle in man and in inoculated animals, which have led them to the following results :—

A. *Structure of tubercle in tissues of connective structure* (Serous membranes, pleural and peritoneal new membranes, pia mater, articular synovial membranes, marrow of bones, lymphatic ganglia).—Tubercle in these tissues is sometimes simple, sometimes conglomerate, sometimes infiltrated ; it answers to both types of structure, cellular and fibrous.

I. *Cellular tubercle.*—1. Simple form. In its simplest form tubercle, invisible, or scarcely visible to the naked eye, is formed by a spherical or fusiform swelling of a blood vessel, more rarely of a lymphatic, and by the agglomeration round this swelling of a certain number of cells. If it occurs in a capillary with a single coat, the vascular swelling consists of hypertrophy and hyperplasia of the endothelial cells of a limited portion of the vessel. If it occurs in a capillary with two or three coats, the vascular swelling is produced—first, by an active proliferation of endothelial cells which are arranged like stratified epithelium ; and secondly, by the formation of an embryonic connective tissue at the expense of the external coat of the vessel. 2. Conglomerate form. Conglomerate tubercle, the size of which exceeds that of a millet-seed, is formed by a plexiform intrication of capillaries which have undergone the changes described above. 3. Infiltrated form. Infiltrated tubercle consists of granulation tissue provided with a rich network of capillaries, most of which have a many-layered endothelium, and some of which are transformed into vitreous cylinders or follicular bands.

II. *Fibrous tubercle.*—A series of intermediate forms mark the transition from cellular tubercle to fibrous tubercle. As the progress of the tubercle becomes more chronic, fibrous neoplasm is substituted for embryonic neoplasm.

B. *Structure of tubercle in glandular organs.*—In the glands, the interstitial may alone be concerned, and may give origin to tubercles whose structure is analogous to that of tubercles of the connective tissue. But in other cases the glandular element participates in the formation of the tubercle. It is thus that the seminiferous tubercle of the testicle or the bronchiole of the lung, filled and distended by the products of epithelial proliferation or by pus, constitute a kind of nucleus around which the interstitial tissue transformed into embryonic tissue presents the appearances characteristic of the vascular change, vitreous capillaries and follicles.

C. *Development and course of tubercle.*—Considered as to development, the tubercular neoplasm passes through two successive phases : 1. Formation of nodules. The nodules develope most often on the course of tubular canals, blood and lymphatic vessels, tubes and excretory ducts of glands, are constituted partly by proliferation of the endothelial and epithelial cells of the canal, and partly by a new formation of embryonic or fibrous connective tissue at the expense of the external coat of the canal. 2. Hypertrophic and degenerative stage. The various anatomical elements of the newly-formed embryonic tissue or the pre-existing elements of the normal tissue show a tendency to hypertrophy and to fuse together to form giant cells. This hypertrophic tendency is principally manifested and generally begins in the epithelial elements of the glands and the endothelial elements of the vessels. It ends in a special vitreous degeneration of the anatomical elements and consequent obliteration of the vessels. This in its turn leads to fatty degeneration and irremediable destruction of tissues.

D. *Pathological significance of tubercle.*—The nodular change in the tubular canals of the organs and tissues, as well as the invading progress of the degeneration, differentiates the tubercular process from other inflammations of either a common or specific cause, in the products of which are equally found giant cells and vessels affected with endarteritis and periarteritis.

In the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Portsmouth 16, Brighton 18, Edinburgh 18, Sheffield 19, Wolverhamption 19, London 21, Bradford 21, Bristol 21, Newcastle-upon-Tyne 21, Leeds 22, Birmingham 22, Salford 22, Liverpool 23, Oldham 23, Nottingham 23, Hull 24, Leicester 25, Sunderland 25, Norwich 25, Glasgow 26, Manchester 26, Plymouth 31, and the highest rate in Dublin 36.

The death-rate from the seven principal zymotic diseases in the large towns last week ranged from 1·5 in Brighton, to 5·9, 6·0, and 9·0 in Hull, Dublin, and Plymouth. Measles showed the largest proportional excess in Plymouth, Hull, and Nottingham ; scarlet fever in Sunderland, Dublin, and Bradford ; and whooping-cough in Salford, London, and Manchester. Small-pox caused 13 deaths in London, 7 in Dublin, but not one in any of the other large towns.

In the principal foreign cities, the annual rates of mortality, according to the most recent weekly returns, were —in Calcutta 31, Bombay 37, Madras 40 ; Paris 33 ; Geneva 23 ; Brussels 30 ; Amsterdam 39, Rotterdam 29, The Hague 29 ; Copenhagen 25 ; Stockholm 33 ; Christiania St. Petersburgh 51 ; Berlin 25, Hamburg 31, Dresden 21, Breslau 32 ; Munich 38 ; Vienna 33, Buda-Pesth 36 ; Rome 52, Naples 52, Turin 34 ; Venice 32, Alexandria 35 ; New York 25 per 1,000 of the various population. Small-pox caused 55 deaths in Paris, and fever 77 deaths in St. Petersburgh.

# Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

SCOTCH DELIVERANCES ON ALCOHOL.—The excellent inaugural address by Dr. Andrew Buchanan, and that by Professor R. T. Fraser, on "Alcohol," recently delivered, have afforded a large amount of consolation to "moderate drinkers" in Scotland, who have historically experienced its beneficial influence in counteracting the impressions of "contiguity to the melancholy main," and a peculiarly damp climate. Professor Fraser's lecture was delivered on the 26th ult. in the Free Assembly Hall, Edinburgh, under the auspices of the Edinburgh University and New College Temperance Society. Professor Calderwood presided, and there was a large attendance of somewhat noisy students. Professor Fraser, after stating that he was not a total abstainer, proceeded to consider, first, the physiological effects of alcohol on the stomach and digestion. When a small quantity was introduced into the stomach it increased the amount of blood in the walls of that organ; it caused the gastric juice to be poured out abundantly, and it stimulated the muscular fibres to contract, so that the movements of the stomach were increased. The beneficial effect of that was that digestion was rendered more rapid and complete. The frequent repetition, however, of doses of alcohol in too concentrated a form resulted in changing the structure of the stomach, so that food was no longer properly digested. By alcohol also, even in small quantity, the heart was quickened and contracted more forcibly, and the small blood-vessels everywhere present on the surface of the body became dilated. Similar changes in the pulsation of the heart were produced by imbibing tea. When the minute vessels were dilated, and at the same time the force of the heart contractions was increased, the supply of blood became augmented, and as that was the condition required for greatest functional activity, organs and structures did more work. The common opinion that alcohol was a stimulant was quite justified by every day observation of its effects upon the brain, upon appetite, upon digestion, and upon the general state of the body of which they spoke as fatigue. After severe bodily fatigue a person was frequently unable to do justice to the food placed before him. Why? Simply because the fatigue had extended itself to the heart and blood-vessels, and the food swallowed failed to excite the circulation, and accordingly failed to produce that flow of gastric juice which was required for the digestion of food, and without which there was no relish for it. They must then either take rest or excite the circulation, and there was no more effectual way of accomplishing that than by drinking a small quantity of alcohol. Discussing the question of the food value of alcohol, the learned Professor held that the results of the most recent investigations had led him to the conclusion that alcohol was a food which increased the weight of the body by retarding the metamorphosis of old tissue, promoting the formation of new, and limiting the consumption of fat. It had also stood the test of being able to maintain the nutrition of the body, while absolutely no ordinary food was being taken. He admitted that people could work as well without it as with it, and that the addition of alcohol to the diet might even diminish the capability for physical exertion. At the same time it appeared to him that its use in moderation was attended with some advantages. Its action on the brain produced effects which were not invaluable to society. The use of that word led him to remark that the mere existence of civilised societies was at present attended with many conditions which made it extremely difficult for a normal and perfectly healthy man to exist. Fatigue, mental and physical, would occur; their digestive functions would become disordered, their appetites would occasionally fail, and for each of these conditions alcohol in moderation was occasionally a valuable remedy. As a general standard of moderation he adopted one ounce of alcohol in twenty-four hours. One ounce of alcohol was contained in two ounces of brandy, five ounces of the stronger wines (port and sherry), ten ounces of the weaker wines, such as claret, hock, and champagne, and twenty ounces of the stronger descriptions of malt liquor. Five ounces would be about two ordinary wine glasses, and ten would represent about a tumblerfull. In the course of the lecture Professor Fraser also spoke of the effects of alcohol on the respiratory and nervous system, and of the bad results to those organs which attended its immoderate use. In conclusion, the lecturer adverted to the social evils connected with immoderate drinking, and expressed the belief that while total abstinence was a valuable protest against these evils, he had more hope of their amelioration in the diffusion of education, and a better attention to the sanitary and hygienic state of the houses of the lower classes. Something might be more speedily done by the suppression of public houses in such localities. Professor Saunders proposed a vote of thanks to Dr. Fraser.

HEALTH OF GREENOCK.—The medical officer's report for this town, submitted to the Police Board on the 16th inst., showed that for the month of February the death-rate was 19·8 per 1,000, a decrease on the three previous years at the same period. The majority of the deaths were from diseases of the respiratory organs. During the month 14 cases of infectious diseases were removed to the hospital. Mr. Mackay, the intelligent sanitary inspector of the burgh, reported that 678 house-to-house visitations had been made.

EDINBURGH NEW TOWN DISPENSARY.—The annual meeting of the subscribers to the Edinburgh New Town Dispensary was held in the Bible Society's Rooms, St. Andrew's Square, on the 16th inst. Mr. Christophers Douglas in the absence of Professor Maclagan, presided. The report by the managers stated that during the past year 10,046 cases had been attended to by the medical officers connected with the institution, and that 2,058 of the sufferers had been visited and attended to at their own homes. The managers called attention to the fact that although the number of patients still continued large, the subscriptions had for the last few years been steadily decreasing, and last year to such an extent that the revenue fell short of the necessary expenditure by over £100. Considering, however that from 9,000 to 10,000 sick poor had been relieved annually by the dispensary, the directors thought themselves justly entitled to ask, not only continued, but increasing, support. The financial statement showed that the subscriptions for the year amounted to £271 5s. 4d., being £102 less than the expenditure.

MORTALITY IN GLASGOW.—For the week ending with Saturday, the 13th inst., the mortality of Glasgow was at the rate of 26 per 1,000 per annum, against 23 in the preceding week, and 25, 24, and 33 in the corresponding periods of 1879, 1878, and 1877.

BEQUEST OF £50,000 TO THE UNIVERSITY OF EDINBURGH.—By the will of the late Dr. Andrew Vans Dunlop, 18 Rutland Square, the residue of his estate, amounting it is believed to about £50,000, has been left to the University of Edinburgh. Of the total amount £30,000 will, it is understood, be paid over immediately to the University authorities, while the other £20,000 is life-rented to a relative of the deceased gentleman. In his will Dr. Dunlop states that £3,000 of the bequest is to be applied to the general fund of the University, and the remainder employed in founding sixteen "Vans Dunlop Scholarships," of the annual value of £100 each, tenable for three years. It is also provided by the will that the first six scholarships created shall be for medical students, while the others are to be equally divided amongst students of the following classes: Chemistry, English Literature, Classics, Political Economy, Logic and Moral Philosophy, Natural Philosophy, Mathematics, Natural History, and Engineering.

## THE EXAMINERSHIP IN THE IRISH COLLEGE OF SURGEONS.

THE seat on the Surgical Court of Examiners of the College, vacated by the death of Dr. O'Leary, M.P., will be filled up on the 1st of April.

The candidates who have as yet offered themselves are Dr. Jacob, who, to compete, vacates his seat as a Councillor, Dr. Kilgariff, Dr. Kendal Franks, Mr. Abraham, the Curator of the College, who is about to present himself for the Fellowship of the College, in order to conform to the bye-law which requires the Examiner to be a Fellow, and Dr. Spencer, the Assistant-Librarian. The election will be, as usual, by seven of the Council, chosen by lot, and the Fellows have been called in compliance with the Charter to witness the choice of an Examiner. Whoever may be elected will have to submit to a further election on the first Tuesday in May, when, under the terms of the Charter, the entire Court will be chosen for the ensuing year.

◆

## Literature.

### OBSERVATIONS ON FATTY HEART, &c. (a)

ON the subject of this essay the author is entitled to be heard with great deference. He has long studied and repeatedly written upon it, and with the history and elucidation of it his name will be for all time honourably associated. Fatty disease of the heart has been a favourite subject of study in the Dublin school, and Dublin physicians have contributed largely to our present knowledge of it. It is therefore only right that it should continue to be cultivated there.

It is but just to observe at the outset that the essay is essentially clinical, otherwise grave fault might be found with it on the ground of pathological deficiencies and total absence of microscopical details. Even as a clinical memoir it should have included at least a few well-noted and briefly narrated cases illustrative of the author's views and confirmatory of them by the results of post-mortem examination, general and microscopical. This remark applies with special force to his observations on the character of the pulse in "fatty growth," and of the respiration in fatty degeneration of the heart. Notwithstanding these deficiencies, which we trust will be supplied in a future edition, and some laxity of style which no doubt escaped the author's attention, and will be corrected in the next issue, the value of the work as the result of long clinical study by a careful and independent observer is beyond question. From the preceding observations we would not be understood to agree with the author in all his conclusions; indeed, we differ from him on many points, as will appear in the sequel.

In chapter i. a general sketch is given of fatty accumulation in health and disease in man and the lower animals, and it is remarked that the "fatty diathesis" is usually accompanied by a tendency to serous effusion "into the nervous structures," a circumstance to which the author would attribute the transitory character of many of the symptoms. The voluntary muscles are often involved, concurrently with the heart, in fatty degeneration; this is especially true of the diaphragm, the consequent debility of which may be taken as accounting for many symptoms hitherto unexplained.

The disease is divided into the two commonly recognised forms of "fatty growth" and "fatty degeneration;" but while these are described as types, and as occasionally distinct, they are, as the author remarks, usually associated in the same organ. Hence, as already remarked, the importance of pathological details in reference to the *specific* value of symptoms.

Fatty growth upon the heart, which may amount to from three to six ounces, is a disease of middle age, and may be diagnosed according to the author from (a) "a large full pulse beating at the natural standard of frequency; (b) evidence derived from percussion of the heart's dulness being more extended than natural; (c) the possible presence of a soft murmur over the aortic orifice, occupying the first sound of the heart only, and leaving the sound normal; and lastly, (d) the condition of the individual as to his being fat or becoming so." "If," adds the author, "all these be present the diagnosis may be looked on as certain," but the absence of murmur would not affect it, as murmur in his experience, and he quotes Quain in confirmation, is present only in the proportion of one in every five cases.

We shall now briefly comment on the evidence of "fatty growth" upon the heart as arranged under the foregoing heads by the author. Assuredly "a large and full pulse beating at the natural standard of frequency," and, as remarked further on, "in some instances jumping," would, in itself, be regarded by most physicians as evidence of hypertrophy with dilatation of the left ventricle and dilatation of the arteries. Fatty growth upon the heart might, and frequently does, coincide with these conditions, and when present it can modify the pulse only by enfeebling or deranging the latter in proportion as it encumbers the heart or replaces its normal structure. The author adverts to the coincident weakness of the pulse; we are therefore, in the absence of post-mortem proof to the contrary, which has not been adduced, justified in suggesting that muscular hypertrophy with dilatation of the left ventricle coincided with fatty growth in these cases. The possibility of this is admitted by the author, who remarks, "indeed, in some rare cases I got the impression that a certain amount of hypertrophy of the muscular texture was present." We incline to regard the combination as by no means rare, indeed, we look upon it as the rule rather than the exception, and in this light the characteristics of the pulse, weakness included, as described by the author, are eminently suggestive of fatty growth upon the heart.

Increased area of precordial dulness could, in this connection, only mean enlargement of the heart, but before the latter can be attributed to fatty growth upon the organ, the ordinary form of enlargement, hypertrophy, must be excluded. Now we hold that left or outward displacement of the point of apex pulsation is *the* pathognomonic sign of hypertrophy, and yet, to our astonishment, the author has not dwelt upon it as an element in the differential diagnosis. If, *with* outward displacement of the apex the pulse were feeble in a case otherwise suggestive of fatty growth upon the heart, we should regard the diagnosis of the twofold condition of left ventricular hypertrophy and fatty growth as warranted; and if, *without* it under similar circumstances, fatty growth alone is established. We hold, in short, that extended precordial dulness without reference to the apex point, cannot be regarded as in any degree symptomatic of fatty growth, but reference being had to the position of the apex, and to the state of the pulse, it may be eminently suggestive of that condition.

The presence or absence of murmur the author would regard, and very properly, as of no significance in relation to the diagnosis of fatty heart, because, although frequently associated with it, murmur is not of the essence of that affection. He concludes from his own observations, and from Quain's tables, that valvular disease is present only in the proportion of 1 in 5 of all cases of fatty disease of the heart. We have no doubt whatever this is an under-estimate; but in relation to this point it is necessary to distinguish between fatty growth and fatty degeneration, and between primary and secondary degeneration. Of fatty growth on the heart, muscular hypertrophy of the organ in some degree is an antecedent condition in the proportion of fully nine-tenths of the cases, and with fatty growth fatty degeneration in some one of its stages, and more or less extended from the outer towards the inner surface of the heart, will, on careful microscopic examination, be found associated in at least nine out of every ten cases. Now, with hypertrophy of the left ventricle, all forms included, valvular disease is associated as cause or concomitant change in the proportion of at least one-third of all cases. Hence it would follow that valvular disease should coincide with fatty growth in nearly the same proportion. Our impression is that the proportion is even larger, not much, if at all, short of half the number of cases. Hayden's cases, referred to by the author, 22 in number, carefully observed and noted during the last illness, and examined after death generally and microscopically with great care, yield, in reference to this point, the following results: Muscular hypertrophy of the heart, and "fatty growth" upon it, 10 cases; and of these 5 presented disease of the valves. In 5 the valves were normal; the aorta was atheromatous in 5, and unaffected in 2; and fatty degeneration of the muscular fibres existed in 9.

---

(a) "Observations on Fatty Heart." An Essay by Henry Kennedy, M.B., Fellow of the King and Queen's College of Physicians, Physician to Simpson's and the Whitworth Hospitals, &c. Baillière, Tindall, and Cox, London. Fannin & Co., Dublin.

In regard to fatty degeneration without fatty growth, the case differs only in the greater proportion of valvular disease. The secondary form of this change (consecutive to hypertrophy) is numerically greatly in excess of the primary. Indeed, we are convinced that this is the proximate cause of death in the majority of cases of cardiac hypertrophy, "failure of the heart" being the result of this change. Amongst Hayden's 22 cases we find 9 exhibiting hypertrophy with fatty degeneration of the heart without fatty growth, and of these 6 presented diseased valves. In 1 the heart was normal as to size, and in 1 it was atrophied, the valves in both these cases being sound. The fact would seem to be that valvular disease was the primary affection in these cases, hypertrophy and fatty degeneration following in succession, fatty growth being precluded by the attendant impairment of nutrition. Primary fatty degeneration is comparatively rare, and but seldom associated with disease of the valves, which, when present, is nearly always located in the aorta, and associated with advanced changes in the coats of that vessel. To these the valvular change is no doubt consecutive by extension, and often of the character described by the author, viz., "smooth, enlarged, and fatty." The valves are, however, not unfrequently calcareous and spiculated, giving rise to reflux as well as obstruction, and of course to a double murmur.

We agree with the author in holding that the coronary arteries are not more prone to atheromatous change than other arteries of the same size. Some judicious remarks are made upon the "arcus senilis." It is most frequently exhibited in the upper segment of the cornea; the circle is occasionally complete, but always more advanced in the upper portion, and in some instances the ring is double. Of the value of this as a symptom of fatty disease of the heart the author forms a comparatively low estimate. We think it indicates tissue degeneration which may or may not implicate the heart. Ossification of the costal cartilages is of similar significance; it is oftenest met with in gouty subjects. Fits are not usual, but we think occasional vertigo, temporary obscuration of sight, and faintness, are common symptoms of fatty degeneration of the heart. The author would regard pain and a feeling of weight in the head with somnolency as indicative of incipient serous effusion on the brain. Seeing that these symptoms are usually of brief duration, we should rather interpret them as evidence of temporary intracranial remora. But "serous apoplexy," of which the author has witnessed many examples, we believe to be of frequent occurrence. Recurrent local paralysis, preceded by a "flabby" state of the affected muscles, an "unwashed" appearance of the skin, gradual loss of flesh, and lowering of temperature, and a "faded leaf" appearance of the face, are noticed by the author as significant symptoms. Shortness of breath in speaking, and local congestion of the face, we cannot regard as having any special diagnostic value.

In regard to "Cheyne-Stokes" breathing, which the author thinks due to fatty degeneration of the pneumogastric, he makes the very interesting remark that placing the patient on the side at once arrests it. Puerile respiration, without any obvious change in the lungs to account for it, is likewise mentioned as an occasional symptom; it is obviously kindred to the preceding symptom and a neurosis of the respiratory nerves and centre.

We think the vomiting noted by the author is due to congestion of the portal system; we have always found it associated with enlargement of the liver, epigastric tenderness, and a moist and loaded tongue. In regard to physical signs, Quain is referred to as having found only four examples of systolic murmur in eighty-three cases noted by him. But out of Hayden's twenty-two cases, not less than twelve presented the signs of disease of the aortic valves, viz., eight an aortic systolic murmur, two an aortic diastolic murmur, and two a double aortic murmur. Thus, more than half the entire number of cases presented evidence of disease of the aortic valves, and in all these cases such disease was actually found after death.

A sense of choking at the upper part of the chest, especially at night, is mentioned by the author as a common symptom in these cases. When the left heart is chiefly engaged, cerebral symptoms take the lead, and when the right heart, pulmonary symptoms are the most prominent. Slow pulse is attributed to fatty degeneration of the *par vagum.*

We should suppose that such a change, by impairing the "inhibitory" function of these nerves, would rather quicken than slow the pulse. Our own impression is, that the slow action of the heart, so remarkable in many of these cases, is due to defective irritability from fatty change of the cardiac ganglia.

The impulse of the heart is weak, in many cases not perceptible, and the sounds are usually indistinct, but in a few cases abnormally clear. In the latter, we should say that the walls of the heart had become attenuated, and the aorta highly atheromatous.

"Pernicious anæmia," and "general paralysis of the insane," are looked on by the author as allied to diseases of this class (fatty degeneration).

Chapter iii. is devoted to prognosis. Under this head, the great mortality from acute disease, especially typhus, among fat people, is remarked. But the previous habits of such persons, who are usually indolent, and great eaters or drinkers, are potent factors in these results; but we agree with the author, that irrespectively of general obesity, fatty disease (degeneration) of the heart is of the worst possible augury in acute disease, in itself even of the most trivial character; the pulse, as remarked by the author, becoming very rapid.

The prognosis in cases of fatty degeneration of the heart is, of course, gloomy; but with favourable surroundings, and by great care, including moderate exercise both active and passive out of doors, cold-catching being strictly guarded against, the patient may survive many years. Chloroform, even in the smallest quantity, should be strictly prohibited.

In regard to etiology (chapter iv.) the author inclines to the opinion that the initiatory change is inflammatory, and has its seat in the nerves; hence the flying pains often felt at the outset of the case in the heart and other affected muscles. We have repeatedly had our attention directed to these transient pains, and without accepting unreservedly the author's explanation of them, we deem it of much interest and importance.

Chapter v., which is devoted to treatment, is decidedly the best in the book, as might have been expected from the eminently practical bent of the author's mind. That alcohol has a certain nutritive value we agree with the author in regarding as proven by the obesity consequent upon an almost exclusive use of it, but we cannot subscribe to his denunciation of milk. Spirituous liquors are no doubt indispensable in the treatment of these cases, but milk, if used likewise within the limits of moderation, will not be likely to develope gout and increase obesity. Drink of any kind should be restricted, and full meals, especially supper, forbidden. The author suggests as a "reminder" the use of mechanical constriction of the epigastrium where the appetite is in excess of the wants of the body. The *fucus vesiculosus* and *liquor potassæ* are recommended as "anti-fats." In the cases characterised chiefly by evanescent and recurrent cerebral symptoms—indistinct articulation, failure of memory, drowsiness, momentary loss of consciousness and local paralysis, an alterative course of mercury, extending over ten or fifteen days, is recommended, and the perchloride is preferred. Prolonged coma from serous effusion, and œdema of the lungs, are likewise best treated with mercury cautiously given after Law's method. Angina pectoris is most often associated with fatty heart in gouty subjects, and in them the attack, if not followed by a copious deposit of lithates in the urine, is sure to be repeated. Opium, ether, brandy, &c., constitute the medicinal agents in the treatment of this formidable complication. and if the attack follow a heavy supper, as it often does, a stimulant emetic should be promptly administered.

Amongst the most unfavourable symptoms sudden rise of temperature, moaning in sleep, shallow breathing, raving (without fever), and loss of the usual appetite are mentioned.

Having now completed, at much greater length than we had intended, but by no means in excess of its merits, our review of this useful work the result of many years' careful study, and especially useful as a concise guide to diagnosis and treatment, and having freely pointed out its defects, which are comparatively few and unimportant, we have no hesitation in recommending it as a most valuable contribution to the literature of the all-important subject of which it treats, and in conclusion, we beg to congratulate the author on the completion of his task.

# Correspondence.

## THE MORTALITY OF ROME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is not a question of personal views, but of *facts*—not a question of opinions, but one of figures—that I intended to raise when in opposition to the returns about the mortality of Rome published in your excellent paper I quoted those of our official *Stato civile.* The same difference is again observable between yours, or the figures by your Registrar-General and the following ones, which I copy again from our official returns :—

*Weekly Mortality of Rome per* 1,000 *Inhabitants.*

| | | | | | |
|---|---|---|---|---|---|
| Week ending with | | Nov. | 15th, 1879 | 27·2 | per 1.000 |
| ,, | ,, | ,, | 22nd, ,, | 31·8 | ,, |
| ,, | ,, | ,, | 29th, ,, | 29·6 | ,, |
| ,, | ,, | Dec. | 6th, ,, | 24·7 | ,, |
| ,, | ,, | ,, | 13th, ,, | 30·5 | ,, |
| ,, | ,, | ,, | 20th, ,, | 34·0 | ,, |
| ,, | ,, | ,, | 27th, ,, | 39·5 | ,, |
| ,, | ,, | Jan. | 3rd, 1880 | 34·8 | ,, |
| ,, | ,, | ,, | 11th, ,, | 34·6 | ,, |
| ,, | ,, | ,, | 18th, ,, | 39·8 | ,, |
| ,, | ,, | ,, | 25th, ,, | 42·6 | ,, |

Your Registrar-General, from whom your figures were taken, receives the very same publication of our *stato civile* from which mine are also copied. Then comes the question—How can it happen that two public officers, working upon the same materials, should arrive at such different results? As far as I have been able to make it out the explanation is this :—

Rome has a fixed population, which is calculated at the end of each year, and at the date of the 1st January, 1879, amounted to 295,232 inhabitants, and on the 1st January, 1880 amounted to 296,960. But beyond this fixed one, Rome, has a floating population of visitors (or two-thirds workmen) which, during the winter, amounts to 50,000 or even 60,000; that is to say, that the population is increased by one-fifth or one-sixth of the regular one. It is evident that this increase must proportionally give its contingent of deaths, and therefore, to fairly establish the percentage the whole number of deaths ought to be distributed not upon the 298,960 inhabitant, but upon the 350,000, or whatever the real weekly number of persons present at Rome should be. But the *stato civile* does not possess the means of exactly determining the number of individuals present at Rome in each week, and therefore it has adopted another plan, which consists of deducting from the whole number of weekly deaths all those of people not belonging to the fixed populations. Both these systems of calculating the proportion per 1,000 are correct, but surely the plan followed by your Registrar-General of taking the number of deaths belonging to a population not registered amongst the inhabitant of Rome, and distributing it upon the whole of the real inhabitants to swell up the mortality of a place, cannot be correct! What has truth, what has science to gain by adding to the percentage of deaths of a place the deaths of inhabitants belonging to other cities? Following such a plan, the most unhealthy city in Christendom (to use an expression of your paper, page 152, No. 2,132) would precisely be those spas or winter residences where dangerous patients or invalids are sent in search of health. I do not pretend that your Registrar-General should adopt this plan of calculation only for Rome; what I say and maintain is that the plan followed by your Registrar-General is erroneous, and therefore that many deductions grounded upon its ciphers are false. In fact, all its ciphers of mortality concerning Rome will, chiefly during the winter months, give one-fifth more higher rate than the real mortality, this is proved by comparing the ciphers of our *stato civile* with those of the Registrar-General.

There is no doubt that the winter months amongst the Roman inhabitants, and chiefly amongst the lower orders, prove the most mortiferous, and in proportion with the cold, deaths chiefly from pneumonia, increase. Therefore this winter, which has been the coldest on record, has given the highest ciphers, each week on average being one-third more than the corresponding one of last year in mortality. For high classes and rich people, who can preserve themselves from cold, this season has proved, till now, particularly healthy. As soon as the summer comes the number of deaths considerably diminishes, and the yearly mortality, which in the last two years, 1877, 1878, had gone down to 23·4 to 23·0 per 1000, in the year 1879 is further reduced to 22·4 per 1,000. You will admit that this is not bad for the most unhealthy city in Christendom, as Rome is called in the quotation above—an assertion proved by giving the erroneous ciphers of your Registrar-General.

I wished to ascertain if, amongst foreign visitors the death-rate was also diminished, as it is amongst the Romans in the last years, and I took the mortality list from the Protestant burial ground from 1871, since the administration was changed, and I divided these by three years, as in the table here shown, the mortality of the Protestants in Rome from 1871 to 1879 inclusive :—

*Deaths of Foreign Protestants in Rome from* 1871 *to* 1879 *inclusive ;—*

| | | | | | |
|---|---|---|---|---|---|
| 1871 | 17 | 1874 | 20 | 1877 | 13 |
| 1872 | 23 | 1875 | 15 | 1878 | 17 |
| 1873 | 15 | 1876 | 20 | 1879 | 11 |
| Total | 55 | Total | 55 | Total | 41 |

So the last three years have given also amongst English and American visitors the same diminution of yearly mortality that we have certified amongst the Roman inhabitants.

These figures were given to me by the kindness of Rev. Dr. Nevis, Rector of St. Paul's Church, the American Church in Via Nazionale. I must ask leave to quote a part of a letter addressed by him to me with the above-given notices :—

"Of 53 cases of Americans that have come under my personal notice 18 deaths were from typhoid fever and 35 from other causes. None of them were from Roman (malaria!) fever. Of the 18 cases of typhoid 14 were persons who either came with fever from Naples or fell ill within a few days after their arrival in Rome from Naples. I find from the record of the cemetery that in the past eleven years three persons described as Americans have died of Roman (malarial) fever. These cases all happened in the month of August, and in years when I was absent from Rome."

I could not help quoting observations which so admirably confirm the statements of my previous letter, and coming from a foreigner and not a medical man, will be regarded as unsuspected of any partiality.

And now I hope not to trouble you again upon this subject. I had on writing to you only one object in view—to re-establish the truth as it is proved by facts and ciphers. The statistics, honestly and scientifically studied, have dissipated a great many illusions in Italy, and excited the activity of the Italians to provide for and to repair many disorders, and so the physical and hygienical conditions of Rome have been considerably improved, and I hope it will continue to improve, now that the yearly returns evidently demonstrate how advantageous to public health have been the measures already adopted and the improvements made.

D. PANTALEONI, M.D.

102 Ripetta, Rome.

## QUESTIONS REGARDING CHLORAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly insert in your next issue the following questions regarding chloral :—

1st. Does its continued use in large doses produce insanity?

2nd. Does the use of it, say for six months, weaken the mental faculties ? and if so, is this weakness of mind permanent afterwards ?

3rd. Does it ever produce paraplegia, muscular irritability, palpitation of the heart, nervousness, &c.?

4th. From what is known about it, would you be disposed to recommend it in the treatment of any disease ?

5th. Is Liebreich right in concluding that this agent leaves no bad after-effects ?

If you will kindly give me any information with regard to proper answers for the foregoing questions you will much oblige,

Yours faithfully,
T. E. C.

[Hydrate of chloral is a moderately good hypnotic and diminisher of pain, but varies much in its action upon different persons. With some it agrees perfectly, and does not appear to lose its effect ; and we know one such case (chronic painful disease of the knee) in which a drachm of the Pharmacopœial syrup has been used nightly for upwards of six years with undiminished benefit. With others, on the contrary, it rapidly loses its effect—the dose has to be increased, until at last marked depression of the heart's action compels the entire discontinuance of the remedy. It occasionally produces palpitation of the heart, nervous depression, or even slight paralysis ; but these symptoms invariably disappear on the drug being left off ; we have never known it to produce insanity. It is essential that pure crystallised hydrate (such as Liebreich's) should be employed ; and a very moderate dose of chloral may be made to produce all the effects of a large one by the addition of half the quantity of potassium bromide. The action of hydrate of chloral is undoubtedly due to diminution of the vascularity of the nervous centres. There is some difference of opinion whether it actually relieves pain ; our experience is that it does so to a moderate extent, but not so decidedly as the salts of morphia.—Ed. Med. Press and Circular.]

◆

## MEDICAL TESTIMONY AGAINST VIVISECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Would it be quite in vain to ask you to publish in the *Medical Press* the enclosed letter from Dr. R. G. Butcher, so valuable to the cause of anti-vivisection ?

Faithfully yours,
Alice M. Swifte,
Hon. Sec. Irish S. A. V.

Whitechurch Lodge, Rathfarnham.
March, 10th, 1880.

"Dublin, Feb. 18, 1880.

"Sir,—In answer to your letter, I beg to state that I firmly believe that no advantages to science can follow the cruel and demoralising practice of Vivisection. Such an exhibition must be a disgrace to the cold, heartless, and would-be scientific professor, and most detrimental to the gentle and kindly feeling of the class of students that should be compelled to witness this sad cruelty.

"I hope you may bring opinion to bear so powerfully as to blot out this stain upon human nature.

"I have, &c., yours faithfully,

"Richard Geo. Butcher, M.R.I.A.,
M.D. (honoris causâ) of the University of Dublin ; University Lecturer on Operative Surgery and Surgeon to Sir Patrick Dun's Hospital ; Examiner on Practical and Operative Surgery in the University of Dublin ; late Senior Surgeon to Mercer's Hospital and Lecturer on Clinical Surgery ; Honorary M.D. of the College of Physicians of Philadelphia ; ex-President of the Royal College of Surgeons of Ireland ; Fellow, Licentiate, and Member of the Council of that body, and for many years President of its Surgical Court of Examiners ; likewise Examiner on Surgery, Anatomy, and Physiology in the College for many years ; Member of the Royal College of Surgeons of England ; Corresponding Member of the Surgical Society of Liège ; Author of a large work on Operative Surgery, of over one thousand pages, largely illustrated ; and of several other Surgical Works.

"P.S.—I give you full permission to publish this letter."

[On the principle that "the exception proves the rule" we are not indisposed to print Mr. Butcher's letter, nor are we surprised that the anti-vivisectionists should make the most of such a prize, for, as far as we know, Mr. Butcher is the first, last, and only medical man of any position or authority who has pledged himself to unqualified disapproval of vivisection. Indeed, the other medical practitioners who have taken similar ground are marked by a uniform insignificance and obscurity, and are usually of that grade in the profession which finds it necessary to advertise itself by any and every means which presents itself. We may, however, say without, we hope, any offence to Mr. Butcher, that though he is undoubtedly a surgeon of the highest rank and great experience, he has always been a representative of the school of practical executive surgery rather than of the modern school, whose creed is based upon physiological inquiry. Mr. Butcher is not likely to have had leisure, inclination, or inducement to look up the physiological or therapeutic fruits of vivisection, and his opinion on such a subject will therefore have less weight with those who know the purely practical nature of his professional avocations (of which the outcome is the "large work on Operative Surgery of over one thousand pages, largely illustrated," above referred to) than with those who may regard the author as a close inquirer into physiological and pathological therapeutics.]

◆

## Novelties.

### IMPROVED PISTON FOR SYRINGE.

Messrs. John Weiss & Sons have patented an invention which promises to be of very material service in the general practice of medicine. It consists of an arrangement by which the loosening experienced in the packing of the pistons of subcutaneous, and other injection syringes, is avoided ; and thus the instrument is always ready for immediate use. The accompanying figure represents the the piston of an ordinary subcutaneous instrument. A in fig. 2 is a vulcanite disc, or cup-shaped sucker, attached to the end of the piston rod, in place of the packing, the disarrangement of which is such a frequent source of annoyance in practice. The material resists the action of such fluids as are used in the syringe, and its edge being made very thin it fits always accurately to the ribs of the tube, thus ensuring a sufficiently complete vacuum. By its use, leakage, or the introduction of air within the tube, are rendered impossible, and we cannot doubt that it will be widely adopted and appreciated by the profession. It need hardly be added that the vulcanite piston can be adapted to any sized instrument.

Brudenell Carter, F.R.C.S., John Cockle, M.D., Walter Coulson, F.R.C.S., A. E. Cumberbatch, F.R.C.S., W. H. Day, M.D., T. S. Dowse, M.D., Sir Joseph Fayrer, M.D., Clement Godson, M.D., F. de Havilland Hall, M.D., Thomas Harvey Hill, Constantine Holman, M.D., Malcolm Morris, Edmund Owen, F.R.C.S., H. E. Sewill, Heywood Smith, M.D., J. C. Thorowgood, M.D., L. S. Forbes Winslow, M.D,

## A GLYCERINE BAROMETER.

THE inexhaustible usefulness of glycerine has received another illustration by the erection at the Kew Observatory of a glycerine barometer, the invention of Mr. Jas. B. Jordan, of the *Mining Record* office, where it is to be rigidly tested. The advantage it possesses over mercury is that its indications of minute atmospheric variations are more easily observable, and it is thought that for meteorological stations, collieries, and some other such institutions, this facility would be of advantage. Glycerine varies an inch where mercury only varies one-tenth of an inch ; but the mean height of its column against the air pressure is 27 feet. A difficulty in the use of glycerine occurred in the fact that the exposed surface freely absorbed moisture, but this has been overcome by covering the surface exposed in the cistern of the barometer with a layer of heavy petroleum oil prepared specially for the purpose. The barometer fixed at Kew has its cistern in a room below that where the observations are taken, so as to obtain the necessary length of column. About three-fourths of a gallon of glycerine, coloured red by aniline, were required to fill it.

## NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. BARR's letter is in the hands of the writer of the article, and will appear with editorial comment in our next.

A PROVINCIAL FELLOW.—The announcement was quite correct. Meetings of the Clinical Society took place on two successive Fridays because of "Good Friday" falling on the regular night.

AN INQUIRER.—In the public conduct of this Journal we espouse neither side in politics or religion ; our care is to look after the best interests of the profession. If you refer to our annotation last week on "Parliamentary Candidates" you will see we ask the votes of medical men for medical men, quite irrespective of party.

MR. BIRCHALL.—We should be happy to give it insertion were it suitable for our columns.

MR. WILLIAMS.—We believe Messrs. Corbyn, Stacey, & Co., High Holborn, are the sole importers.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 8 p.m., Mr. Warren Tay, "On Sterno-mastoid Tumours."—Dr. Little, "On a rare form of Wry-neck and certain Pathological Changes of the Face resulting from the Deformity."

DUBIOUS.—You need have no doubt at all on the subject ; it is one of the worst and most dangerous of the patent medicines ; its sale should be prohibited.

DR. T. H.—We regret the delay with yours and other accepted communications. Almost every number this year has contained four or eight extra pages, but we have still an accumulation of arrears which is gradually being reduced.

LIVER PADS.—The editor of the *Eclectic Medical Journal*, of Cincinnati, has made a post-mortem examination of one of Holman's liver-pads, and reports as follows :—"The pad is made of drilling, and filled so as to be about one-half to three-fourths of an inch in thickness. The contents are : Ground flaxseed and ground fenugreek seed, 50 per cent. ; pitch, resin of galbanum or olibanum, and resin of sandarac, 45 per cent. The remainder is probably composed of aromatics. The fenugreek gives the peculiar odour, though this is changed to a limited extent by the resins and aromatics."

THE CLERK OF BOYLE UNION.—Letter received — under consideration ; will be referred to in our next.

HARVEIAN SOCIETY OF LONDON.—Thursday, April 1, at 8.30 p.m. Dr. Cavafy. "A Case of Urticaria Pigmentosa."—Mr. Malcolm Morris. "A Case of Pemphigus Cured by Arsenic."—Mr. Reeves, "Rectal Stricture with special reference to Rectotomy and Twenty-five Colotomies."

ERRATUM.—"THE DIGESTIVE FERMENTS AND ARTIFICIAL DIGESTION." —The Maltine Manufacturing Company have drawn our attention to the statement contained in the above "special" article in our last issue, that "Malt or Maltine is now procurable from a variety of makers." The manufacture of, and the use of the word "Maltine," is the exclusive right of this Company, and is therefore unlike other malt extracts, as it cannot be made by any other house.

## VACANCIES.

Balrothery Union, Kilsallaghan Dispensary.—Medical Officer. Salary, £125, with fees, and £20 as Medical Officer of Health. Election, March 27.

Boyle Union, Keadue Dispensary.—Medical Officer. Salary, £120, with fees, and £10 as Medical Officer of Health. Election, March 31.

Celbridge Union, Lucan Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Medical Officer of Health. Election, April 12.

Edinburgh University.—Examinership in Clinical Surgery. Applications to the Secretary before April 5.

Great Northern Hospital, London.—Physician for Out-patients. Honorary. Applications to the Secretary before March 31.

Irvinestown Union, Ederney Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election, April 3.

Torbay Hospital.—House Surgeon. Salary, £100, with board. Applications to Mr. W. H. Ritson, Hemsworth, Torquay, before Mar. 30.

Sudbury Union, Suffolk.—Medical Officer for the Fourth District. Salary, £62, with the usual extras. Applications to the Clerk before March 29.

Westminster Hospital.—Medical Registrar. Salary, £40. Applications to the House Committee before March 31.

## APPOINTMENTS.

CARTE, W., F.R.C.S.I., Medical Officer to the Kilmainham Prison.

CROWE, J. W., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Workhouse and District of the Hartlepool Union.

DOYLE, G. W., M.B., Medical Officer to the Fifth District of the Norwich Union.

GABBETT, H. C., M.B., L.R.C.S.I., L.K.Q.C.P.I., Assistant Physician to the Royal Hospital for Diseases of the Chest.

HURST, G., B.A., M.B., House Physician to the General Lying-in Hospital, London.

HUTCHINSON, J., F.R.C.S.E., Consulting Surgeon to the Royal Hospital for Diseases of the Chest.

MACASKIE, J. G., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Eastern District of the Belford Union.

MACKENZIE, J. A., M.B., C.M., Medical Officer to the Dispensary for Sick Children, Gartside Street, Manchester.

NORTHEY, W. C., M.R.C.S.E., Medical Officer for the Tavistock District and the Workhouse of the Tavistock Union.

SCOTT, W. E., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Second and Eleventh Districts of the Lincoln Union.

WHITE, W. H., M.D., M.Ch., L.K.Q.C.P.I., Assistant Physician to the Royal Hospital for Diseases of the Chest.

WILLES, W., M.R.C.S.E., L.R.C.P.Ed., Resident Surgeon to the Royal Sea-bathing Infirmary.

ARMY MEDICAL SERVICE.—Surgeon-Major W. P. Ward is placed on retired pay, with the honorary rank of Brigade Surgeon ; Surgeon-Major M. G. Jones is granted retired pay, with the honorary rank of Brigade Surgeon ; Surgeon-Major G. A. Davidge is granted retired pay, with the honorary rank of Brigade Surgeon ; Surgeon-Major G. N. Irving, M.D., from half-pay, to be Surgeon-Major.

NAVY MEDICAL SERVICE.—Staff Surgeon M. Rodgers, M.D., has been promoted to the rank of Fleet Surgeon in her Majesty's Fleet, with seniority of 6th inst.

## Births.

ALCOCK.—March 12. at 14, Shanganagh Terrace, Ballybrack, the wife of Surgeon-Major N. Alcock, of a daughter.

LOVEROCK.—March 12, at Ballyjamesduff, the wife of R. G. Loverock, L.R.C.S I., of a daughter.

WINCKWORTH.—March 16, at Shefford, Beds, the wife of C. E. Winckworth, L.R.C.P.Lond., &c., of a daughter.

## Deaths.

BARLOW.—March 18, at Norfolk House, Albion Road, Dalston, Matilda Mary Ann, wife of R. Barlow, M.R.C.S.

BELL.—March 13, at The Wakes, Selborne, Thomas Bell, F.R.C.S., F.R.S., aged 88.

CRACKLE.—March 9, at Ilkestone, Derbyshire, Thomas Arthur Crackle, M.R.C.S.E., aged 31.

DAVIES.—March 11, at The Court, Merthyr Tydvil, Edward Davies, M.R.C.S.E., J.P., in his 78th year.

GOOLDEN.—March 10, Richard Henry Goolden, M.D. Oxon., F.R.C.P., of 1 Sussex Gardens, Hyde Park, W.

MAUNSELL.—March 16, at Aldershot, Madeline Cecilia, the wife of Surgeon-Major S. E. Maunsell, A.M.D., aged 36.

METGE.—March 15, at Coolgraney, Gorey, Sarah Maria, wife of James Metge, M.B.

MIMPRISS.—March 14, at his residence, Wandsworth Road, Thomas R. Mimpriss, M.R.C.S.E., in his 85th year.

### ON AFFECTIONS OF SPEECH. (a)

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P. Lond.

Dr. J. Hughlings Jackson has contributed to some recent numbers of *Brain* three important articles "On Affections of Speech from Disease of the Brain." His aim being always to illustrate abnormal conditions by a clear conception of the normal conditions of mental life, he is able by his familiarity with the best results of modern psychological analysis to exemplify in a singularly full and complete manner the close correlation between the two. This is seen, for example, in the prominence which he gives to the idea of cerebral disease as a process of dissolution, the reverse of the process of evolution as defined by Mr. Herbert Spencer. But the exigencies of pathological interpretation have also compelled him to go beyond accepted truths in psychology, and his papers contain some very suggestive ideas as to the nature of the normal mental processes.

In the first article (*Brain*, III.) he begins by remarking on the manifold character of affections of speech. Thus it is not enough to study speech "morphologically," that is, in reference to the geographical position of the centres concerned; it must be studied "anatomically," that is, in relation to the anatomical connections between the centres and the parts of the body represented there. And so we must say that the substratum of words "is made up of nerve-cells and fibres representing some particular articulatory movement." Again, the method must not be partly anatomical and physiological, partly psychological, but the phenomenon must be consistently viewed on both the objective and the subjective side. Once more, these special cases of nervous disorder cannot be dealt with methodically apart from other kinds of nervous disease. Loss of speech must be studied in the light of the facts of loss of images or "imperception" (in delirium). Aphasia has also its analogue in hemiplegia, since in both we can trace degrees of dissolution, that is of reduction of actions from the least to the most highly organised. As our subject has to be studied empirically at first, we must adopt rough classifications. First of all loss of *speech*, due to extensive disease of the brain, must be distinguished from loss of *articulation*, due to complete paralysis of the tongue, &c., and from loss of vocalisation, due to disease of the larynx. Again we must draw a distinction between intellectual and emotional language, and say that while the speechless patient has lost the former he has not lost the latter. That is to say, the patient may be able to use the words (*e.g.*, "yes" and "no") interjectionally, but not propositionally. The affections of speech are very different in degree and kind according to the exact seat and extent of the disease. We may roughly mark off three degrees: (1) *Defect of Speech*, in which the patient has a full vocabulary, but confuses words; (2) *Loss of Speech*, in which the patient is practically speechless and his pantomimic is impaired; and (3) *Loss of Language*, in which, besides being speechless, he has altogether lost pantomimic, and emotional language is deeply involved.

We begin with (2), "complete aphasia," as the simplest. In noting this condition we must (as in the case of all nervous disorders) carefully observe both the patient's negative and positive condition—that is, what he has lost in language as well as what he retains. First of all, then, his negative condition is summed up by saying: (*a*)—He does not speak, that is, utter anything of real speech value. (*b*) He cannot write. The last defect shows he cannot speak internally (a fainter degree of external utterance). (*c*) He cannot read to himself (in most cases). (*d*) Lastly, his power of making signs ("pantomimic propositionising") is impaired. His positive condition is described as follows:—(*a*) He can understand what is said or read to him, showing that though "speechless" he is not "wordless." (*b*) His articulatory organs move well in eating, &c. (*c*) His vocal organs, too, act apparently well (he may be able to sing). (*d*) His emotional language is apparently unaffected. Thus he smiles, frowns, and varies his voice properly. This condition is only to be understood by a reference to the fact that the patient possesses the images symbolised by words. The patient's perception and recognition of things is unaffected. Thus he will point to familiar objects which are named in his hearing: he recognises drawings, and even handwriting, though he cannot read what is written. So, again, he can copy writing, and copy print into writing, though unable to write in the sense of expressing himself. This shows that he has not lost images, and has not wholly lost words, though he has lost "the words used in speech." That is to say, he retains "an automatic service of words." Besides the comparatively unimportant distinction between internal and external speech (which is one of degree only), there is a very important distinction between "the prior, unconscious, subconscious, or automatic reproduction of words, and the sequent, conscious, and voluntary reproduction of words: the latter alone is speech either internal or external." This duality in the verbalising process corresponds to a duality in the revival of the images symbolised. Thus, when a man in delirium takes his nurse to be his wife, it is because in his sane state the first stage of his recognition of her as a woman would be the subconscious automatic reproduction of his, or one of his, well-organised symbol-images of woman, of which the one most organised would probably be that of his wife. There is evidence for saying generally that it is the right half of the brain which acts when the first subconscious service of words begins, the left when there follows that verbal action which is speech. The activity of the right half is also supposed to be that which underlies the understanding of another's words. The writer concludes this article by commenting on "emotional aphasia," which he regards as no real loss of speech at all.

---

(a) Abstracted from *Brain* by Mr. James Sully.

In the second article (*Brain*, VI.) Dr. H. Jackson goes more into the details of the positive side of the case called by him loss of speech. He admits that there is something like speech left, but contends that this is of the very lowest, most completely organised kind. The utterances made by the patient are either (1) *Recurring Utterances*, or (2) *Occasional Utterances*.

(1) *Recurring Utterances* consist (*a*) sometimes of jargon as "yabby," "watty," &c.; (*b*) in other cases they are made up of words which to a healthy person are speech, as "man," "awful"; but since they come out at all times, they mean no more than the jargon. Their only function is that of emotional expression. In truth, the patient sings his recurring utterances. (*c*) Sometimes, again, the recurring utterance is a phrase, as "come on," which, though it has a propositional structure, has no propositional function in the mouth of a speechless patient. (*d*) A common relic of speech with the speechless patient is a recurring "yes" or "no," or both these words. Sometimes this is all that is left; at other times it is found along with utterances taken from the other divisions. The peculiarity of "yes" and "no," is that while they may be propositions (being "proposition words"), they are not always this. Thus some patients may simply use "yes" and "no" interjectionally as an expression of feeling without meaning assent or dissent. Others again may reply by help of these "proposition words," showing that they are not absolutely speechless. And, finally, in many cases, besides having the emotional service of these words, and being able to reply with them, the patient can say "yes" or "no" when told to do so, thus showing that he has the full use of them. The presence of this additional power of reproducing the words "yes" and "no" when told, marks an important distinction in speech affections. To sum up the result of the inquiry into Recurring Utterances, the only real exception to the rule that the speechless patient has absolutely lost speech, is the case in which "yes" and "no" are used in reply (propositionally); and this exception is very significant, since these words are "the two most general, most automatic of all his propositions." "Yes" and "no" really stand on the border line between emotional and intellectual language, being used by healthy people now in the one way now in the other. (Thus "yes" may simply express a feeling of sympathy as well as imply assent to a proposition, and "[illegible] indicate mere surprise.) Hence the retention of these two most perfectly organised of all propositions is strictly in accordance with the principle of dissolution.

(2) *Occasional Utterances* are rare, with the exception of oaths, which are much more frequent. They may be classed serially as (*a*) Utterances which are not speech; (*b*) Utterances which are inferior speech; and (*c*) Utterances which are real speech. Under (*a*) fall "bad language" ejaculations as "Bless my life," which are brought out under some strong excitement and cannot be repeated. They are among the best organised emotional ejaculations. Class (*b*) includes such utterances as "Wo, wo!" once brought out by a patient when standing by a horse. They are true speech, but inferior speech ("superior" and "inferior" as applied to speech referring to the degree of precision of application to new relations of things). That is to say, they are well-organised utterances prompted by special but often-recurring circumstances, and admitting of no variation in correspondence with new situations. Group (*c*) comprises very rare utterances which are perfect speech, being adaptations of words to special and new circumstances. Thus one of Dr. Jackson's own patients said in reply to an inquiry by his son as to where the former's tools were, "Master's," which involved adaptation to new circumstances. Such a case presents great difficulties. It is impossible to say whether the reproduction of this proposition was owing to the frequency of its repetition before the disease came on, or to the strong emotional interest excited by the question. (The man was very poor, and his tools a matter of real importance to him.) Neglecting these very rare utterances, we see that a speechless patient may possess some "rags and tatters" of real speech, which represent the best-organised part of his language. It is probable that this residual highly organised utterance takes place by help of the right half of the brain, that part which appears to serve in the first automatic reproduction of words. It is to be supposed that while every process of verbalising, like every other process, is dual, the more automatic the process is the more fully and equally is it represented in each half of the brain.

It still remains, however, to account for the use of those recurring utterances which do not at first appear to be the result of such highly organised nervous arrangements. In the third article (*Brain*, VII.) Dr. H. Jackson takes up these cases, giving fuller examples of recurring utterances. When the recurring phrases, which, as observed, are always used emotionally, are not common exclamations, like oaths, we may account for their recurrence by the hypothesis "*they were being said, or about to be said, when the patient was taken ill.*" To make this intelligible it is needful to enlarge more fully on the distinction already pointed out between the two services of words, subconscious or automatic and conscious, connected with the two sides of the brain. Speech is to be regarded as but the second half of a whole process which may be called *verbalising*. We can say that it includes two propositions, a "subject-proposition," followed by an "object proposition." "It is supposed that the subject-proposition is the 'survival of the fittest' words in fittest relation during activity beginning in the right half of the brain," and that it "symbolises an internal relation of two images, internal in the sense that each of them is related to all other images already organised in us." On the other hand, "the object proposition symbolises relation of these two images as for things in the environment, each of which images is related to all other images then organising from the environment." Thus "the two propositions together symbolise an internal relation of images in relation to an external relation of images." Dr. H. Jackson bases this distinction on Mr. Spencer's definition of a psychological proposition as componnded of two propositions (*Psychology* I., p. 162). We have to suppose, then, that the words of the recurring utterance constituted the last subject-proposition (not completed to an object-proposition) when the patient was taken ill. In some cases it is possible to support this hypothesis by a reference to the facts. Thus the recurring utterance of a railway signalman taken ill on the rails was "Come on to me," or simply "Come on," and the pathetic utterance of a clerk who lost speech and became paralysed after hard work in making a catalogue was "List complete." If this hypothesis be correct, such utterances stand at the opposite extreme to that of old and perfectly organised utterances. They correspond to the latest and newest nervous actions. We have to suppose that in the healthy man there remains after every last utterance for a short time a slight degree of independent organisation of the nervous arrangements concerned; for without assuming this we cannot understand how it is possible to recollect what has just been said, and so to speak consecutively. In the case of the speechless man we must suppose that this normally temporary activity of nervous arrangements becomes permanent. There are strong reasons for saying that these recurring utterances are due to the activity of the right half of the brain. The left half is known to be extremely damaged. To say that the disease caused the utterances is absurd, for disease is simply a process of destruction. The positive mental symptoms arise during activity of lower centres or lower nervous arrangements which have escaped injury. Why they should arise after the injury is probably to be explained by the supposition that "destruction of functions of a higher centre is a removal of inhibition over a lower centre." We must say, then, that while disease *causes* loss of speech, it *permits* the increasing dischargeability of the right half of the brain. This increase of excitability on the removal of inhibition is commonly considered to be only temporary, but the particular activity may be kept up by repeated use; and this accounts for the recurrence of the utterance. In the case where there was no recurring utterance besides the deeply-organised "yes" or "no," we have to suppose that when the patient was taken ill there was no subject-proposition "organising." And so there was nothing to interfere with the simple course of dissolution—namely "reduction to the most automatic of all propositions." What applies to recurring utterances of propositional form probably applies also to jargon, which may be viewed as "made up of fragments of the words or phrases the patient was about to utter when taken ill." Thus it may be conjectured that the woman whose recurring utterance was "me," "pittymy," or "committyme," &c., was saying when taken ill "Pity me, come pity me." This mixing up of words is illustrated by a reference to what takes place in slighter cases of aphasia, and even in a normal condition, as the utterance by a healthy man of "mukes from Boodies" for "books from Mudie's." These troubles of speech are probably due to hurried activity of the right half of the brain, involving a conflict of strong and sudden nervous discharges during a state of emotional excitement. Such emotional excitement would naturally arise during the setting in of the illness; hence the frequency of confused speech or jargon among forms of recurring utterances. A similar line of remark applies to those recurring utterances which are clearly emotional, and consist of interjectional expressions, as "fire!" "help!" We may suppose that in these cases the process of dissolution effected by the disease was so rapid and so deep that only the most organised utterance had a chance of surviving. "To recapitulate: By considering (1) the external circumstances at the time of the being taken ill; (2) the intensity of the emotional state under which the last attempt at speech was made; and (3) the gravity of the lesion, we may perhaps be able to show why this or that kind of recurring utterance remains in particular cases of speechlessness."

We now pass from the second kind of aphasia, loss of speech, to the first kind, defect of speech. Here the patient may be able to get out a word, or even a reply, as "very well," and go on uttering it in rejoinder to further questions, to which it is irrelevant, being aware of its irrelevance. It becomes, in fact, a temporary recurring utterance. This "barrel-organism" (to use a phrase of Gardiner) shows itself also in writing. It seems doubtful whether the patient is able to repeat what he has said when he is told to do so. We must distinguish between the ability to say something for the sake of saying it and the ability to speak. The inability of the patient to say "no" when told to do so is of the same order as his inability to protrude the tongue when told to do so. Hence it will be well to consider this feature of aphasia in connection with other losses of voluntary power in disease. To understand these we must revert to the hypothesis of the duality of the mental action, applying this now to the process ending in voluntary action instead of that ending in perception or ideation. In voluntary operations we suppose there is a preconception; the operation is nascently done or "dreamt" before it is actually done. Thus, before I put out my arm I must have a "dream" of the hand as being already put out. To "will," to "know," to "intend," to "try," to "remember," are all names for this subjective reproduction which precedes objective reproduction. In the case of voluntary action the subjective order of the "dream" is the opposite to that of the actual operation; thus the image of the final stage of the movement, or rather its result, must precede the representation of the intermediate stages. And it is probable that subjective states always arise in an order the opposite to that of the corresponding objective states. It is pretty certain that this is so in some dreams where a noise develops a dream, though the consciousness of it may come last in the dream it excites. So it is supposable that when we say "gold is yellow," the subjective order may be "yellow," "gold," "for our concern is first with the yellowness of gold, not with gold." In the case of automatic actions, too, there is probably a "dream," though here the movement has so often followed the "dream" that the two are nearly equally perfect and easy. Now, when the patient tries to put out his tongue, or to say "no" when told, and fails, we have to suppose that a subjective reproduction or "dream" takes place without the second stage of objective reproduction.

Dr. H. Jackson concludes this paper by touching on other kinds of nervous affection which show something analogous to permanent "barrel-organism" (recurring utterances) of speechless patients. In these cases where temporary unconsciousness results from some injury, we find that operations going on when the unconsciousness supervened remained nascent during the period of total unconsciousness, and became active again during the restoration to consciousness, at the end of which stage they ceased. Such restoration means the return of control from higher centres, which is impossible in the case of "speechless" patients in whom the higher centres are destroyed.

◆

## THE COMPULSORY REMOVAL TO HOSPITAL OF PATIENTS SUFFERING FROM INFECTIOUS DISEASE. (*a*)

By J. F. POLLOCK, A.B., M.B. Dub., L.R.C.S.I., L.K.Q.C.P.I.,

Medical Officer of Health, Blackrock, Rathdown Union; late Professor Medical Jurisprudence Dr. Steevens' Hospital Medical College.

The subject to which I beg to call your attention, as it stands, is a very important one, as the health of a whole neighbourhood may be involved therein, and one single patient treated in his own home, where the means of isolation is inadequate, might be the cause of spreading infection over a large area of a populous district; but taking it as a question, in the abstract, it would seem to be one which would be hardly necessary to embody in the form of a paper to be brought before this Society, as it might be

---

(*a*) Read before the Society of Metropolitan Medical Officers of Health, Dublin, March 10th, 1880.

said you have an Act of Parliament on the subject and all you have to do is to act in accordance with it; but if you will consider the matter well, you will find there are a number of questions difficult to decide upon, and it is on these questions I would wish to elicit the opinions of the members of this Society.

Now the first question is, What are our actual powers in the removal of patients so infected?

The 141st section of the Public Health Act (Ireland), 1878, provides that "where any suitable hospital or place for the reception of the sick is provided *within the district of a sanitary* authority or within a convenient distance of such district, any person who is suffering from any dangerous infectious disorder, and is *without proper lodging or accommodation*, or lodged in a room occupied by other persons not suffering, or is on board any ship or vessel, may, on a certificate signed by a legally qualified medical practitioner, and with the consent of the superintending body of such hospital or place, be removed by order of any justice to such hospital or place at the cost of the sanitary authority, and any person so suffering, who is lodged in any common lodging house, may, with the like consent and on a like certificate, be so removed by order of the sanitary authority."

Now let us analyse this section, and in the first place consider what is meant by "any suitable hospital or place for the reception of the sick within a convenient distance of such district." Of course in cities and large towns throughout Ireland there is generally a hospital within the district of a sanitary authority, but as the Act does not apply to either alone, but to villages, small towns, and rural districts, what would you consider to be "a convenient distance?" For example, let us take my own immediate locality, the only place for the reception of every form of infectious disease is the union hospital, which is upwards of five miles from the district: would you consider it safe to remove a patient with an infectious disease (on whom the rash, if any, is coming out) to such a distance? for recollect, in our capacity of conscientious medical men, we must consider the safety of the patient as well as how to check the progress of the disease. I am not one of those who consider that even one life should be sacrificed for the benefit of the community at large. I do not think any of us here present, if it concerned ourselves, are sufficiently philanthropic to approve of vicarious sacrifice.

Buck in his new work on Public Health recognises the importance of considering the patient's life. He says, "Should a patient be found in a house where isolation is impossible, such as a hotel or tenement, if it be possible to remove him *without seriously compromising life*, the case should be removed to hospital."

In a memorandum of the Privy Council printed in the Appendix to the first Report of the English Local Government Board, it is recommended that "each village should have the means of accommodating instantly and in a few hours' notice, say four cases of infectious diseases in at least two separate rooms *without requiring their removal to a distance*."

Now if the patients who should happen to be removed chance to die, the invariable cry is, the patients would not have died if you had left them in their own homes and not removed them so far; and then the difficulty occurs of being unable afterwards to remove any other patient, except by compulsory means, as they are afraid of the like fate. I am not drawing an exaggerated picture; it is what occurs and has been said hundreds of times.

The 155th section of the Public Health (Ireland) Act, 1878, provides that "any sanitary authority may with the sanction of the Local Government Board provide for the use of the inhabitants of the district hospitals or temporary places for the reception of the sick or convalescent, and for that purpose may itself build such hospitals or places of reception or contract for the use of any existing hospital, or part of a hospital or place for the reception of the sick or convalescent, or may enter into an agreement with any person or body of persons having the management of any hospital for the reception of the sick or convalescent inhabitants of the district on payment of such annual or other sum as may be agreed upon."

Now if you should consider four, five, or six miles too far for the removal of a patient, is it advisable or practicable for the medical officers of health to recommend the sanitary authorities to provide proper hospital accommodation within a convenient distance?

I myself think that five or six miles is too far, if it could be avoided, to be compatible with the safe removal of patients, and in cases of epidemic disease I consider every sanitary authority should, if it was at all practicable, provide a small hospital or temporary place for the reception of the sick within, say, a mile of the district, if there is no hospital within a convenient distance.

The next question I wish to draw your attention to in section 141 is, What is meant by "without proper lodging or accommodation, or lodged in a room occupied by other persons not so suffering?"

I will not dwell long on this beyond asking the members of this Society what their views are on the point?

The opinion held by most sanitary authorities is that this section refers only to the occupiers of tenement houses and not to persons living in their own self-contained houses, *no matter* what size, provided they are in their own premises. I think, if this is not the limited view you would take of this section, it would be well that this Society should record what interpretation they would put on it, and thereby remove the impression which is at present held.

Allowing that we do not hold this limited view, what interpretation would you put on the words "without proper lodging accommodation"? I presume your answer will be, "you would take into consideration the position of the premises in close contact with other cabins, its sanitary state and the cubic area of the rooms as well as the number of the apartments and the number of the inhabitants;" but I do not think that there is one law for the poor and another for the rich, and if you take into consideration the cubic space, size, and position of the house, you must also recollect that we are frequently called upon to treat infectious diseases in private houses situated in crowded positions where the cubic space of the rooms is below what is generally allowed, and if you enforce the Act in connection with the poorer classes, you should also carry the enforcing of it into all classes of society. Can we or would we do this? The poor person who has his own self-contained house considers he has as much right to keep the sick members of his family in his own house as any person in a better position.

Now I will just allude to the *mode of conveyance* for infected persons. Section 140, states "that every sanitary authority shall provide and maintain a carriage or carriages suitable for the conveyance of persons suffering under any infectious disorder, and shall pay the expense of conveying therein any person so suffering to a hospital or other place of destination, and shall keep such carriage or carriages properly disinfected."

This section I think should be carried out by every sanitary authority, but the question sometimes arises, as it has arisen in my own district, Where is such a conveyance to be kept? Should not the sanitary authority provide a proper place, and if so at what distance, if any, from any inhabited place? You may think this question futile and unnecessary, but when I tell you that when I endeavoured to urge my own sanitary authority to provide a proper carriage, the cry was, "We will not have a carriage which has carried infectious persons kept in the Town Hall or any place within the boundaries of the town." In fact, a few years ago a second-hand cab was provided for the purpose, but it produced such a panic, being kept in the town, that it was sent off to the union hospital, which I have already told you is five miles off; and if I now require to remove a patient, I cannot do so until the following day, and then the vehicle sent by the guardians is a kind of cart covered with a canvas awning over it, and if the day should happen to be inclement, I defy draughts to be kept out; and is it safe to remove a patient in such a kind of vehicle?

In reference to a proper mode of conveyance, I think it would be well if this Society would suggest what kind of conveyance would be most desirable for the removal of patients. If each member would bring at some future meeting an outline of a plan he would suggest, a vote could then be taken as to which was the best, and have it recorded accordingly for the benefit of sanitary authorities in general.

I think that any kind of ambulance recommended should resemble, as much as possible, an ordinary vehicle in general use, as the appearance of a sick van in a populous district invariably causes a panic; and I think that should be avoided for many reasons, one reason chiefly being the objection the patients themselves have in going in anything of the kind.

Now, if the ambulance or carriage resembled an ordinary vehicle, the objection would not be so great, and you would be more likely to get the patient to go; the kind I would suggest would be a carriage resembling a small omnibus, a rough outline of which I here submit to you, by which you see, if necessary, I could remove two patients at a time.

I will now briefly recapitulate the questions on which I wish to elicit the opinion of this Society:—

1. What are our actual powers under section 141 in the removal of patients infected with zymotic disease? and under this question we will place: (*a*) What would you consider to be within a convenient distance of a district? and (*b*) What is meant by without proper lodging and accommodation?

2. Is it advisable for medical officers of health to recommend the sanitary authorities, if practicable, to provide proper hospital accommodation *within a convenient distance?*

3. What mode of conveyance would this Society recommend for the removal of patients to hospital, and where should such conveyance be kept?

I will, in conclusion, throw out a suggestion that occurs to me would be advisable to bring under the notice of Parliament by-and-by, when sanitary science comes more to be understood. At present, you all know that the union hospital combines a workhouse and hospital—the workhouse being for the reception of paupers, and the hospital is used, not only for the paupers who are in the workhouse, but also for those who are honestly endeavouring to support their families by their daily labour. I believe this principle highly objectionable. All dispensary physicians throughout Ireland are well aware of the difficulty there is in getting dispensary patients to go to the poor-house hospital. I am well accustomed to the *almost daily* remark "Oh, I will go to any hospital you send me to, provided you do not ask me to go to the poor-house hospital." I believe these objections chiefly lie, not in the treatment they receive, which I am sure in most cases is as good as they receive in any hospital, but because it is the poor-house. Can you wonder at it, after all? The head of a family is earning his livelihood with the sweat of his brow, and though his profits are not commensurate with those in a better position, still he supports his family honestly, and does not wish to be classified as a pauper; and is not that a feeling which our legislators should take into consideration, and not force persons to lower themselves by allowing them to be so classified? Should we not encourage that self-respect, instead of trying to break it? Rather, should we not try and elevate their social aspect, however extravagant the idea may be, instead of depressing it?

Now the only practical way which occurs to me to carry out the latter idea is to have the hospital separated from the workhouse. To do this, of course, many things have to be taken into consideration. It is clear that most districts could not support a large hospital for itself in addition to the union workhouse on its present footing; but I consider if the workhouse was merely kept for the benefit of the old and physically helpless people, its great expenses could be so far reduced as to allow hospitals for one or more districts to be supported with the aid from Government of very little extra expense.

◆

## Clinical Records.

### CASE OF "STRANGULATED FEMORAL HERNIA" —OPERATION—OPENING OF THE SAC—RECOVERY.

Under the care of FRANCIS J. O'REILLY,
Surgeon Trim Union Infirmary.

JULIA D., æt. 46, laundress, enjoyed good health till 24th December, 1879, when she was suddenly seized with sickness of stomach, accompanied by colicky pains over the abdomen.

The pain and vomiting continuing, notwithstanding the administration of a dose of castor oil, and copious draughts of soda water and milk, I was requested to visit the woman on Friday, the 26th, which was about 48 hours after the commencement of the attack. I found the following condition of things to exist:—

The woman lay on her back with legs drawn up; the eyes appeared sunken, and surrounded by a dark areola; the pulse was quick, but fairly strong; the tongue moist, but evidently becoming dry in the centre; the abdomen was swollen and tympanitic.

A quantity of the vomited matter lay in a basin at the bedside, and was easily recognised as being stercoraceous in character.

The presence of a hernia at once suggested itself to my mind, and, on examining the possible sites of such an occurrence, I detected a swelling in the left femoral region, of the size of a small egg, which was resonant on percussion, and which I had no difficulty in pronouncing a femoral hernia, probably an enterocele.

I tried reduction by taxis immediately, and, failing to produce any effect other than that of causing intense pain even on the slightest manipulation, I had the woman removed to the wards of the Trim Union Infirmary. Here an enema of turpentine was administered, which brought away a large quantity of fæcal matter, but did not exercise any beneficial influence whatever on the hernia.

Without further delay, I had the woman placed fully under the influence of chloroform by my friend Dr. Nicholson, and again applied the taxis, but with the same unavailing result.

I now, having determined to operate, cut down on the hernia in the usual way, and soon exposed the sac, without opening, which I had hoped to effect reduction; but, finding the hernia still irreducible, I brought the intestine into view by a careful incision, and, passing my left index gently over its surface, I was enabled, by re-introducing the hernia-knife, to divide a few constricting bands, an operation which was quickly followed by reduction of the hernia.

The portion of intestine, which alone formed the contents of the hernia, presented a highly congested appearance, and, had the operation been longer delayed, must soon have undergone irreparable change; verifying in this respect the remark of Mr. Hey, that "he had often regretted performing the operation too late, but never having done it too early."

The woman was now removed to bed; a jar filled with warm water placed in contact with her feet, and a draught given her containing fifteen minims of tincture of opium. The draught to be repeated every four hours.

Dec. 27th, 10 a.m.—Slight vomiting occurred after I had left the hospital, due, probably, to the action of the chloroform. Slept well during the night. Felt quite free from pain and sickness of stomach. No swelling of abdomen, or tenderness to touch. Pulse 100; temp. 101°. Had some milk to drink through the night. To have milk in small quantities, and a tablespoonful of cold beef-jelly every two hours. The draught of opium to be continued every four hours.

6 p.m.—Patient had a good day; slept at intervals; no vomiting or pain; bowels unmoved. Pupils showed the influence of opium, which was directed to be continued as before. Pulse 92, fairly strong; temp. 100·2°. Milk and beef-jelly to be given as previously.

28th, 10 a.m.—Slept the greater part of night; free from pain, or tenderness over abdomen. Stated she felt "as well as ever she did." Tongue clean and moist. Pulse 92, fairly strong; temp. 99°. Bowels unchanged; pupils rather contracted. To have egg and milk mixture and beef-jelly as before. The opium draught to be continued every four hours.

29th.—Passed a good night, having slept well. Bowels still inactive. Influence of opium on pupils plainly manifest. Tongue clean. Pulse 88; temp. 99°.

30th.—Enjoyed a night of refreshing sleep; bowels remained locked up; pulse 84; temp. 99°. To have milk, a little arrowroot, and beef-jelly. A draught of opium at bedtime. Two sutures removed from wound, and carbolic acid dressing applied.

31st.—Rested well during the night; pulse 72; temp. normal. To have some beef-tea, and discontinue opium.

Jan. 1st.—Had a favourable night; bowels, however, not having acted yet.

2nd.—Bowels were opened last evening without any bad result, and the patient expressed a desire to be allowed up; a request, it is needless to observe, not complied with.

The history of the case, from the above date to that of the patient's discharge from Hospital on the 18th January, was one of uninterrupted recovery.

# Special.

## THE DIGESTIVE FERMENTS AND ARTIFICIAL DIGESTION.—III.

There are many maladies in which artificial digestion may be resorted to with advantage—take gastric ulcer for instance. Here there is a raw surface, which gives rise to acute pain when the stomach becomes acid in the act of digestion. Further, there is a growth of connective tissue at the base of the ulcer, usually producing an adhesion to the colon if in front of the stomach. Whenever the muscular movements of the stomach commence in the digestive act, then this base of the ulcer is dragged upon and pain produced. Relief is immediately experienced by vomiting the contents of the stomach, when the movements cease, and the stomach becomes alkaline as well as empty. Or again, in chronic gastritis the contents of the stomach are rolled over and over till they become covered with a coating of mucus which forbids all digestion. In both these maladies, as well as in cancer of the stomach, it has been the rule hitherto to restrict the patient to a milk diet—milk sheathed with an alkali, as Vichy water, solutions of soda, or potash, or magnesia, or carbonate of magnesia. In this manner the gastric acidity was neutralised, and the milk soon found its way into the duodenum, and was then subjected to pancreatic digestion. For invalids, convalescents, for patients with fever, or the subjects of acute inflammatory affections, such methods of feeding, so as to tax the powers of the organism to the least possible extent, has long been adopted. On the proper feeding of many a case the issue turns; it is most important, then, that the practitioners be familiar with the most recent knowledge on the subject. Some practical outcomes of Dr. Roberts' researches on the digestive ferments are of much value where the digestive power is weak or absent. The artificial digestion of food is now simple, does not require any costly instruments, and even does not entail any very high intellectual qualities in the nurse, or other attendant upon the invalid. The pancreatic ferment used by Dr. Roberts is a *liquor pancreaticus* prepared by Mr. Benger, of the firm of Motterhead and Co., and is a bland, almost colourless fluid. The dose of this potent elixir is one dessert-spoonful. Along with it it is requisite a strong solution of bicarbonate of soda, which is easily prepared by putting an ounce of the soda into a six-ounce bottle of water, so that a teaspoonful represents ten grains. In order to peptonise milk it is necessary to add the pancreatic fluid and the solution of soda to a pint or so of milk, and keep the whole at a temperature of not more than 157° Fahr. for an hour; after which it should be raised to the boiling point, which arrests all further action of the ferment. There are several points, however, to be attended to in order that this peptonising be done properly. In the first place, if the fermenting digestive act be allowed to go on until the whole of the milk is completely peptonised, the resultant product becomes unfit for food, being repulsive and nauseous. On the other hand, if not carried on sufficiently long the milk is curdled and disagreeable. In about ten minutes the milk thickens, and begins to curdle in a soft curd; this, however, soon passes away, and in about half-an-hour the milk has recovered its original and normal appearance. Consequently, the digestive process should not be arrested until at least half-an-hour shall have elapsed. In half-an-hour, however, only two-thirds of the milk is peptonised; in another half-hour three-fourths of the milk is peptonised. The remaining fourth is not peptonised until another hour and a-half has elapsed; so that to wholly and completely peptonise milk no less than two hours and a-half are required. But milk wholly peptonised is altered in appearance, and is nauseous, so as to be quite unfitted for a food. It is well, then, to arrest the process at the end of one hour, when the milk has regained its normal appearance, and is digested to the extent of three-fourths. Probably the natural digestive ferments of the stomach are equal to the digestion of the remaining fourth. In thus peptonising milk for invalids it is found desirable to bring the mess to the boiling point at the end of the hour, and arrest the digesting process, so as to preserve the appetising appearance of the milk.

Allowing for the different preparations of the pancreatic fluid not being precisely and exactly alike, the following is a satisfactory procedure. A pint of milk is first diluted with half its bulk of water, and then heated to 150° Fahr. (This may be ascertained rudely by sipping the fluid; as soon as it is too hot to sip it is near 150° Fahr.) It is then put into a covered jug with a dessert-spoonful of the pancreatic fluid and two teaspoonsful of the solution of bicarbonate of soda, and placed in a warm place under a "cosey." There it should remain for an hour, after which lapse of time it should be raised to the boiling point. It may then be used like other milk. After being boiled milk so partially digested undergoes no further change until decomposition sets in. It is well, however, to know that this prepared milk does not keep well, and should be consumed within twelve hours of its preparation. Prepared in such small quantities, there could be no reasons for keeping it more than an hour or two, even when the sick individual is an infant. In so preparing milk a temperature of about 150° Fahr. is attained by directing the milk at the ordinary temperature to be diluted with an equal quantity of boiling water, and then going through the process just described.

In his recent address on the treatment of typhoid fever, Sir Wm. Jenner pointed out that milk, if given in too great quantities, was apt to form a curd in the patient's stomach and bowels, and so be detrimental to the patient; but milk prepared as above is free from such contingency, and seems indicated in typhoid fever and allied maladies. Indeed by such peptonised milk one of the greatest difficulties in the treatment of acute diseases is removed very satisfactorily. Where a more nutritive material is desired it is well to do as follows. To half-a-pint of cold milk, in a covered jug, add half-a-pint of well-boiled and *boiling* gruel. This will give a temperature of from 120° to 130° Fahr. To this compound add a dessert-spoonful of the *liquor pancreaticus* and a teaspoonful of the soda solution. Put under a "cosey" as before, and at the end of an hour raise the whole to the boiling point. In this case the trypsin acts upon the gluten in the flour as well as upon the casein in the milk, while the diastase converts the starch into sugar. The gruel employed may be made thin, and may consist of wheat-flour or other farinaceous materials. Such a prepared food will tax but little the feeblest digestive organs, and seems especially adapted to those cases of dyspepsia where a sour or bitter taste is experienced at the end of the digestive act. These unpleasant "bye-products" of digestion would thus be largely avoided. In cases, too, where pain, according to the late Dr. Leared, indicates an insufficient secretion of gastric juice, this compound seems aptly suited. By combining with such a dietary a little bismuth and a bitter the digestion will be greatly improved in most cases, even in very intractable ones. One caution, however, is requisite, and highly requisite, and that is this—If the gastric trouble be reflex, and it very commonly is, being due to a misplaced uterus, or an irritable ovary, then appropriate measures of treatment must be employed; and no scheme of a dietary, however cleverly devised and carefully carried out, can cure these cases unless the source of the gastric irritation be recognised and treated accordingly. But as to our ordinary difficulties in the management of dyspepsia, they are largely removed, whether, due to functional or to organic mischief in the stomach. In certain cases the administration of a dose of the *liquor pancreaticus* with a teaspoonful of the soda solution, at the tail of the digestive act, will prove sufficient; in other cases it may be necessary to have resort to the partially-peptonised milk, or milk and gruel. In either case we will feel that this work of Dr. Roberts's is a solid and valuable contribution to our armamentarium when contending with enfeebled digestion, no matter how associated.

◆

## FRANCE.

(FROM OUR SPECIAL CORRESPONDENT).

Paris, March 20th.

At the Wednesday's meeting of the Academie de Médecine M. Championière presented to the members two women on whom he performed the Cæsarian section, followed by hystero-ovariotomy called "Porro's operation." In each case success was complete. According to the report read before the Academy Mr. Championière performed four times this operation at the hospital, saving the mother in two instances and all the children, but two of the latter succumbed shortly after. Perhaps the details of one of the successful cases may be interesting. A woman, aged 26, primipara, entered the Maternité the 27th Oct. of last year, presenting all the appearances of a distorted pelvis. On examination M. Championière found that the antero-posterior diameter of the brim only measured 73 millimetres. The woman was kept in the hospital for three weeks when she was examined by M. Tarnier, who recognised the necessity of interference, and also advised Porro's operation. On the 19th November, labour having commenced, M. Championière decided on operating. The waters had not yet burst. The uterus was rapidly attained by a large incision measuring sixteen centimetres in the median line, commencing a little above the umbilicus. Immediately the uterus was opened a great gush of blood took place through the aperture. The section quickly accomplished, a living female child was extracted. The placenta having also been drawn out, M. Championière applied two forceps to the edges of the wound, and drew forwards the uterus. Two pins were then passed through the inferior segment of the organ; beneath a wire and between the two pins a second, which were tightened by Cintral's *ligateur*. Section of the uterus, the two ovaries, and the Fallopian tubes followed. The incision in the abdominal walls was brought together with six deep and one superficial suture, and Lister's dressing applied. The operation lasted three-quarters of an hour. The sutures were withdrawn successively up to the 28th. The pedicle separated the thirteenth day after the operation. Cicatrisation was complete on the 20th December, and a week afterwards she left the hospital cured.

At the same meeting M. Fournié read a paper on "The *rôle* of the Eustachian Tube in the Physiology of Audition." According to the author, this tube not only is destined to renew the air in the cavity of the tympanum, and to afford a means of evacuating the secretions of this cavity, but also to prevent intense sounds from resonating in the cavity. Contrary to the opinion generally received, M. Fournié seeks to demonstrate that the Eustachian tube is a canal constantly opened, and that the muscles which are inserted into it, far from being dilators, are constrictors, which close the tube during certain movements, such as are necessitated by speaking and mastication. In fine, the renewing of the air in the cavity is effected by a sort of respiration, in which the constrictors would play the *rôle* of muscles of respiration, whilst the proper elasticity of the tube would replace those of inspiration.

Dr. Kœchler, in the *Annales Obstétrique*, recommends warm fomentations on the head in obstinate uterine hæmorhage, in order to prevent cerebral anæmia and cardiac paralysis. The noises in the ears cease, the pulse becomes more firm, and the patients experience a notable amelioration.

Neumann, of Vienna, in eczema of the scalp, passes a brush imbibed in the following solution over the part affected twice a day:—Borax, alum cryst., āā 5 grammes; glycerine 100 grammes. In eczema of the nose he introduces into the nasal orifice suppositories composed of tannin, 15 centigrammes, cacao butter, 80 centigrammes. The tannin might be replaced by the same quantity of oxide of zinc.

## AMENDMENT OF THE DENTAL ACT.

We understand that the following Memorial has been presented to the Executive Committee of the General Medical Council.

*To the President and Council of the General Medical Council.*
